FRIDAY, NOVEMBER 17, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

ONE-HUNDRED-AND-SIXTY-THIRD SESSION, 1916-1917.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Sixty-Third Session was held on Wednesday, November 15th, when an address was delivered by DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, on "The Stability of Great Britain." (See pp. 5-19, below.) The chair was taken at 4.30 p.m.

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. (unless otherwise announced):—

NOVEMBER 22.—LESLIE URQUHART, "The Financial Position and Economic Development of Russia." THE RIGHT HON. LORD CARNOCK, G.C.B., G.C.M.G., G.C.V.O., K.C.I.E., British Ambassador in Russia, 1906-1910, will preside.

" 29.—DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, "The Internal-Combustion Engine."

DECEMBER 6.—C. M. WHITTAKER, B.Sc., "The Coal-Tar Colour Industry." SIR WILLIAM A. TILDEN, D.Sc., F.R.S., will preside.

" 13.—H. WILSON FOX, "The Development of Imperial Resources."

" 20 (at 4 p.m.).—A. C. BENSON, C.V.O., Master of Magdalene College, Cambridge, "Classical and Scientific Education."

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

DECEMBER 14.—JOHN AITON TODD, B.L., Professor of Economics, University College, Nottingham, "The World's Cotton Supply and India's Share in it."

PAPERS TO BE READ AFTER CHRISTMAS.

LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

J. H. VICKERY, "German Business Methods."

CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

OCTAVIUS C. BEALE, "British Arts and Crafts after the War."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel."

SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

F. A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

January 18, February 15, March 15, April 19, May 17.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

January 30, February 27, March 27, May 1.

HOWARD LECTURES.

Monday afternoons, at 5.0 or 4.30 p.m. (unless otherwise announced):—

JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." Three Lectures. (Five o'clock.)

LECTURE I.—NOVEMBER 27.—The economic importance of coal—Enhanced importance in war time—Coal: the munition of war—The movement for economy—The output of coal and consumption for various purposes—Duration of supplies and economical considerations in relation to other countries—Other alternative sources of energy.

LECTURE II.—DECEMBER 4.—Recent developments in knowledge of composition of coal—Coal as a heating agent—As source of power—For domestic heating, etc.—The by-products from coal distillation, their relation to industry, and particularly as raw materials for munitions of war.

LECTURE III.—DECEMBER 11.—Directions in which economy may be realised—Economy in production—The utilisation of small and low-grade coal—Improvements by suitable preparation for market—Economy in use—By-product recovery—Economies possible from centralised systems of power generation: from extended use of carbonised coal, including gas—Low temperature carbonising schemes.

WILLIAM RIPPER, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

ALAN A. CAMPBELL SWINTON, F.R.S., "Electricity and its Applications." Two Lectures.

January 3, 10.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom: and for meritorious works in the

various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908 the Society was granted the privilege of adding "Royal" to its title.

Fellowship.—At the Annual General Meeting held on June 24th, 1914, a By-Law was made authorising all Members of the Society to use the designation of Fellow.

Ordinary Meetings.—Meetings are held every Wednesday during the Session (November to June), at which papers on subjects relating to inventions, improvements, discoveries, and other matters connected with Arts, Manufactures, and Commerce are read and discussed.

Indian Section.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

Colonial Section.—This Section was formed in 1874 under the title of the African Section. It was enlarged in 1879, to include the consideration of subjects connected with the Colonies and Dependencies. Four or more Meetings are held during the Session.

Cantor Lectures.—These Lectures originated in 1863, with a bequest by Dr. Cantor. The Lectures deal with the latest applications of Science and Art to practical purposes, and are, as far as possible, experimentally illustrated.

Fothergill Lectures.—Courses of Lectures, similar to the Cantor Lectures, are given from time to time under this bequest.

Howard Lectures.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

Shaw Lectures.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

Aldred Lecture.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

Cobb Lectures.—Funds have been provided for occasional Lectures in memory of the late Mr. Francis Cobb.

Juvenile Lectures.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Fellows during the Christmas holidays.

Admission to Meetings. — Fellows have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Fellow can admit two friends to the Ordinary and Sectional Meetings, and to the Cantor and other Lectures. Books of tickets for the purpose are supplied, but admission can also be obtained on the personal introduction of a Fellow. For the Juvenile Lectures special tickets are issued.

Journal of the Royal Society of Arts.—The *Journal*, which is sent free to Fellows, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

Examinations.—Examinations, founded in 1854, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education and Music. Full particulars of the Examinations can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Fellows, who are also entitled to borrow books.

A History of the Society has lately been published (John Murray, pp. 558, 15*s.* net) and can be obtained from any bookseller. It gives a history of the Society's work from 1754 to 1880.

Conversazioni are held, to which Fellows are invited, each Fellow receiving a card for himself and a lady.

Election of Fellows.—Candidates are proposed by Three Fellows, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

CALENDAR FOR THE SESSION.

The following is the Calendar for the Session 1916–1917. It is issued subject to any necessary alterations:—

The Juvenile Lectures will be given at Three o'clock.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 15th, 1916; Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barstow, Hon. George Eames, Barstow, Texas, U.S.A.
Brooker, Hon. Charles Frederick, A.M., The American Brass Company, Ansonia, Connecticut, U.S.A.
Cameron, Alexander, Government Dockyard, Massaruni, British Guiana.
Carver, George W., The Tuskegee Normal and Industrial Institute, Tuskegee, Alabama, U.S.A.
Clerk, Mrs. Dugald, Lukyns, Ewhurst, Surrey.
Cossar, Wilayat Hussain, The Watan, Lahore, India; and The University, Glasgow.
Currimbhoy, Hon. Sir Fazulbhoy, 13, Esplanade-road, Bombay, India.
Daubeney, Rev. A. R. Vaughan, East Walton Vicarage, King's Lynn.
Dhar, His Highness the Raja of, K.C.S.I., Dhar, India.
Eddy, Charles B., 62, Cedar-street, New York City, U.S.A.
Fenimore, Miss Beulah A., 147, Manheim-street, Philadelphia, Pennsylvania, U.S.A.
Garrett, Miss Mary S., Belmont and Monument Avenues, Philadelphia, Pennsylvania, U.S.A.
Glynes, Webster, Hamston House, Kensington-court-place, W.
Goodwin, William V'Alters Summers Gradwell, J.P., F.G.S., Red Heath, Silverdale, Staffordshire.
Greenwood, Thomas, 10, John-street, Hill-street, Mayfair, W.
Haidar, Haji Saiyid Jalaluddin, M.A., Aitchison Chiefs' College, Lahore, India.
Higgin, William Henry, B.Sc., The Elms, Parkstone, Dorset.
Holeman, Frederick Alfred, M.I.E.S., Jibutil Gold Mines, Morriston P.O., South India.
Horsfeld, H. E., Cuttack, Orissa, India.
Humphreys, J. Charlton, Junior Athenæum Club, 116, Piccadilly, S.W.
Hutton, J. Arthur, 15, Cross-street, Manchester.
Kershaw, Louis James, C.I.E., India Office, Whitehall, S.W.
Khan, Syed Ahmad Ali, Salimpur, Lucknow, India.
Lenygon, Henry, 31, Old Burlington-street, W.; and 16, East 60th Street, New York City, U.S.A.
Limaye, Professor Hari Govind, Fergusson College, Poona City, India.
Lockington, A. H., 1, Howard-road, Westbury, Bristol.
Mackenzie, James, Messrs. Macneill & Co., Calcutta, India.
Marston, Edwin S., 22, William-street, New York City, U.S.A.
Muir, Peter Gillespie, M.I.E.S., Calle Espartero 35, Ferrol, Spain.
Mukerjee, Haridas, Victoria Cottage, 14/3, Upper Circular-road, Calcutta, India.
Murdoch, Frederick Teed, British Consular Agent, Mansourah, Egypt; and Nile Lodge, Queen's Walk, Ealing, W.
Myers, Dudley B., Junior Carlton Club, Pall Mall, S.W.
Myers, Horace, The Sugar Wharf, 188, Harbour-street, Kingston, Jamaica, British West Indies.
Noel, Miss Emilia Frances, 37, Moscow-court, W.
Panday, H., B.A., Archæological Survey, Eastern Circle, Bankipur, India.
Pill, John R. G., M.Am.Soc.C.E., Corona, Alabama, U.S.A.
Rathbone, George, J.P., Ivy Lodge, Aigburth, Liverpool.
Roberts, William Henry, Hollin Royd, Victoria Drive, Eastbourne.
Scott, Henry, A.M.I.Mech.E., M.I.E.S., P.O. Box 42, Te Kuiti, New Zealand.
Shrosbree, Albert de Bois, F.S.I., 5, Clive-street, Calcutta, India.
Singh, Bhagat Lakshman, Government High School, Bhera, Shahpur District, Punjab, India.
Spencer, Professor Matthew Lyle, A.M., Ph.D., 8, Alton-court, Appleton, Wisconsin, U.S.A.
Surridge, William Alfred, 167, Auckland-road, Upper Norwood, S.E.
Tagore, Ranendra Mohun, Purana Baree, 6, Raghunundun-lane, Calcutta, India.
Tearoe, James, M.Inst.C.E., M.I.Mech.E., 409 and 410, Strand, W.C.
Thompson, Colonel Robert Means, Wall-street Exchange Building, 43, Exchange-place, New York City, U.S.A.
Timson, Rowland Clunbury, "And," Greenway, Berkhamsted, Herts.
Watson, Charles Cuningham, C.I.E., Commissioner's House, Ajmer, India.
Whymark, George Harvey, 7, Kyo-Machi, Kobo, Japan.
Wills, Miss Elizabeth, 10, Rock-street, Fall River, Massachusetts, U.S.A.

The Chairman delivered the following

ADDRESS.

Again I have the honour of addressing you as Chairman of Council of the Royal Society of Arts, at the beginning of our one hundred and sixty-third year of active life. Last year I chose for my subject the past achievements of England, and contrasted them with those of Germany. Now I propose to discuss broadly some conditions of the stability of Great Britain and the Empire; and further, to consider some of the changes which are desirable in order to increase our security and prosperity.

Stability in the static sense has no existence

in this world of change, but there is a real dynamic stability such as is seen in the long-continued motion of the bodies comprising a solar system. It is true that any one solar system must have an end, although millions of years elapse; but ultimately the continued existence of a universe of suns and worlds depends not upon the continuance of the units, but upon the infinity of space and star systems. The stability of the world, as we see it, is due to the running down of a stream of energy, and life exists only in the process of flow of energy throughout a system; life ceases to be possible when the flow ceases.

The stability of the British Empire is dynamic; it is a stability of living form maintained alive by incessant change. Our stability is maintained by the perpetual adjustment of our lives to new conditions as they arise, and from the continuous struggle of individual interests there emerge certain interests recognised to be common to the whole body. The first common interest is freedom: freedom to order one's life at one's pleasure, to follow any course thought to produce a sufficient livelihood, and then to cultivate our interest in science, art, literature or sport—whatever we conceive to be necessary for our happiness—without Governmental hindrance; liberty limited only where it would inconvenience our neighbours.

So it happens that within the Empire many diverse courses are energetically pursued by individuals and by our great Dominions, Colonies and Protectorates over the seas. The ideal of Australia is different from that of Canada: New Zealand differs from both, and also from Great Britain and Ireland. The visit of Mr. Hughes showed most clearly the different view-point of the Dominions. Mr. Hughes' ideal differed so much from the British ideal that at times his utterances seemed unintelligible. The key to his attitude and that of the Dominions is found in a recent Address to the Victorian Chamber of Manufactures, delivered by its President, Mr. Herbert Brooks, who stated: "The objective of a self-contained Commonwealth within a self-contained Empire has been with this Chamber from the beginning." That is not the ideal of Great Britain; for nearly three centuries she has attempted to utilise the resources of the whole world. The idea of a self-contained country is possible, and even plausible, in a great continent like Australia, where the area and climate suffice to produce almost everything necessary for comfortable life. It is even possible for Canada, and still more plausible for the country of our great cousins, the United States.

The small area and the isolation of Great Britain and Ireland from the rest of the world by the sea prevented this from becoming the ideal of Great Britain. When Britain led the world about the middle of the eighteenth century from the agricultural to the industrial stage of civilisation, it was rapidly borne in upon her that the growing population could not comfortably subsist on the agriculture of these islands. It was obvious from the straits of the "hungry forties" that it was by no means easy to provide food for even the 24 millions then forming the population; much less was it possible so to provide for the wants of the 46 millions, our present population. Some say that by improved agriculture we should be able to support our population in comfort without external food supplies; and they point to the example of Germany, which, before the war, by intensive cultivation and lavish use of imported nitrates and other fertilisers, had succeeded in greatly increasing her agricultural yield. The argument for a self-contained country from the food point of view is supported by the logic of facts in time of war. Obviously during war a sufficient supply of food from our own soil would be a great advantage; one great danger would be abolished. Germany and Austria-Hungary between them have an area of about 450,000 square miles, and undoubtedly they could in time of peace produce food sufficient to support their population of about 116 millions on a low scale of comfort. The Central Empires have now an admirable opportunity of realising the ideal of the Australian, that of a self-contained Empire. The British Fleet is obliging them to this extent, and is protecting them from commercial attack by the external world. Germans and Austrians should be very happy in the realisation of this self-contained ideal, but apparently their condition is one which they desire to terminate as soon as possible. Their experience of two years has taught them that in times of war it is just possible to exist on the agriculture of their extensive lands, but only in a state of great discomfort and low vitality.

The mean density of the population of the United Kingdom is about 50 per cent. greater than that of the Central Empires, so that what is just possible for them is impossible for us, and accordingly we were forced by facts staring us in the face to embark upon schemes of expansion which would enable us to obtain food and other matters necessary for comfort and luxury

from every part of the world. To purchase these external products from the over-seas portion of our Empire and the other nations it was necessary that we should produce goods and perform services which the world required. This we did in the most successful manner. We manufactured and exported goods to every part of the world; we produced a great fleet to carry our goods and to return with all the products of the earth, and we performed services of the most important kind to the world at large, which have resulted in increasing the productions of the world required by man in every country and clime. From 1750 to the present day Great Britain has led in science, invention, manufactures and finance. From 1830 till 1913 (eighty-three years) Great Britain has steadily increased in the wealth and comfort of its people. This is easily shown by examination of the exports of British produce; the increase of national capital, of total national income, and of population, and income per head. The exports of British goods were, in 1805, 38 million pounds in value; between 1805 and 1830 the value rose to 48 millions, but fell to 38 millions again in 1830. The condition of the people in these early twenty-five years was stationary, but it steadily improved from 1830 to 1913, when the exports rose to 525 millions. This is clearly shown by the following table:—

EXPORTS OF BRITISH GOODS FROM 1805 TO 1913.

Year.	Exports. £	Year.	Exports. £
1805	38,000,000	1880	223,000,000
1830	38,000,000	1890	263,000,000
1840	51,000,000	1900	291,000,000
1850	71,000,000	1910	430,000,000
1860	136,000,000	1913	525,000,000
1870	199,000,000		

The rise in the value of British exports is steady and considerable, and even in the latest period of twenty-three years the increase was from 263 to 525 millions—almost exactly double. This proves increase in trade, but it does not follow that prosperity also increases. The object of agriculture, manufactures and trade is efficiently to feed, clothe and house our people, and the measure of efficiency is expressed in the sum of wealth and the income attained by work of every kind considered in connection with the total population at each period. The earliest attempt to measure the capital wealth of England was made by a British merchant in the year 1600; he estimated it at a total of 100 millions sterling; with a population of 4½ millions this gives £20 per head.

No broadly founded values were obtained till 1865. Capital, population, and capital value per head have increased steadily since that date. This is shown by the table below:—

INCREASE OF TOTAL WEALTH OF THE UNITED KINGDOM FROM 1865 TO 1914.

Year.	Total Capital, United Kingdom.	Population.	Capital per Head.
	£	Millions.	£
1865	6,113,000,000	29·9	204
1885	10,037,000,000	36·0	287
1905	13,036,000,000	42·8	304
1909	13,986,000,000	44·4	315
1914	16,000,000,000	46·0	347

The total capital of the United Kingdom has thus increased from 6,113 millions in 1865 to 16,000 millions in 1914, while the population increased from nearly 30 to 46 millions. Had the total capital value been uniformly divided among the population, each man, woman and child would have possessed property to the value of £204 in 1865 and £347 in 1914. Capital value is difficult to determine with accuracy, because it includes not only material things, such as land, cattle, grain, ships, railways, houses, furniture and clothing, but also immaterial things, such as goodwill of different trades and professions. Total income can be estimated with greater accuracy.

INCOME.

Population and income per year per head have increased steadily since 1867, as shown by the following table:—

INCREASE OF TOTAL INCOME OF THE UNITED KINGDOM FROM 1867 TO 1915.

Year.	Total Income, United Kingdom.	Population.	Income per Year per Head.
	£	Millions.	£
1867	814,000,000	30·5	26·7
1875	1,200,000,000	32·8	36·6
1885	1,350,000,000	36·0	41·3
1907	2,000,000,000	43·6	45·8
1915	2,500,000,000	46·0	54·3

The income of the country has thus increased from 814 millions in the year 1867 to 2,500 millions in the year 1915; and the income per head of the population from under £27 per head to over £54 per head.

The income of the whole British Empire was given as follows by Mr. Edgar Cramond, F.S.S., in a lecture delivered on December 3rd, 1915:—

BRITISH EMPIRE INCOME FOR 1915.

	£
United Kingdom	2,500,000,000
Canada	350,000,000
Australia	230,000,000
South Africa	50,000,000
New Zealand	55,000,000
India	700,000,000
Crown Colonies and Protectorates	150,000,000
	£4,035,000,000

From this it appears that the annual income of the whole British Empire amounts to the enormous total of 4,000 millions, of which the United Kingdom produces 62 per cent., while all the other populations produce 38 per cent. When we consider that the population of the Empire in 1914 was about 400 millions, and that of the United Kingdom only 46 millions, it is most evident that our population, taken as a whole, is industrious and successful.

With regard to Germany, wealth and income have also increased. For the year 1895, Schmoller estimates the income per head of the whole population as £23; but Helfferich arrives at a lower value—£20·5 for the same year; and for the year 1912 Helfferich states the income as £30 per head. For the later year 1914, German Government figures, disseminated by wireless messages, state £32 per head as the value. Taking their own valuations, therefore, for the year 1914, the German income per head amounts to only 60 per cent. of that of the United Kingdom. The state of the German population as to efficiency in 1914 has only reached the stage attained by our population about the year 1874. From this it is evident that Germany must improve greatly in general efficiency before she can even pretend to equal Great Britain.

It has been said that Germany by her competition has diminished our foreign trade; this has been proved to be incorrect by Mr. R. H. O'Farrell in an article "British and German Export Trade before the War" (the "Economic Journal," June 1916. See Appendix).

It is to be remembered that in 1914 the population of Germany was roundly 68 millions, while that of the United Kingdom was 46 millions; so that the total income of the Germans was about 200 millions short of ours. The income per head being so much higher with us, we are in a better position to provide for war; thus our annual savings just before the war amounted to 350 millions, while in 1915 they increased to 600 millions. That large sum can be increased by further limitations in private expenditures, and it may even reach 1,000 millions in the present year (1916). This increase, with the savings possible in both Army and Navy, will relieve us from undue anxiety as to provision of funds for an even longer war than seems in the least degree probable.

Germany's external investments before the war amounted to about 1,000 millions, while ours were 4,000 millions, of which only a small part was placed in Europe and Asia. Germany, by the power of Great Britain's Fleet, is deprived of all access to her foreign investments during war, while we are free to utilise nearly all our foreign securities by calling upon America, our Dominions, Colonies and Protectorates for the supplies required. Further, the Navy has annihilated Germany's foreign trade, on which she depended for a large part of her income; so that while our available income increases, Germany's surely diminishes as the war proceeds. In power of procuring the material things and services required for war, we are in a position of great and undoubted advantage. All the nations of the world were indebted to us; we were the great creditor nation, and our capital placed abroad, which Sir George Paish estimated at 4,000 millions, now stands us in good stead, and together with our other measures places us in a position of secure stability. Of this large sum, Canada and Newfoundland owe 515 millions; Australia, 332 millions; New Zealand, 84 millions; and the United States of America, 754 millions. This capital was necessarily supplied by us to stimulate the growth of food and the production of other materials necessary to our existence. Sir George Paish has well summed up the position as follows: "It is sometimes assumed that the regularity with which we obtain our supplies of food and raw material is merely a matter of destiny, as everything else is; but you will realise that the common-sense of the British people has assisted destiny in providing the capital needed to bring to the shores of Great Britain the fruits of the earth in their due season, and in regular weekly and monthly shipments the endless

wealth that has lain beneath the surface of the earth in countless ages.

"In brief, the economic and financial strength of this country is founded upon the welfare, not merely of the British people, but practically all countries, and it has been built up not by any local or narrow policy, but upon the broadest possible lines."

Had Great Britain followed the Australian and Canadian ideal, neither of the Dominions would have received the assistance of this country's capital. Britain, too, was so broad-minded as to put no restrictions whatever upon the Dominions because of the capital received. For example, the 36 millions a year going to Canada, it appears, was mostly used by the Canadian people for the purpose of buying goods from the United States, and that country in turn used the money so placed to its credit in London for the purchase of tea from India, silk from Japan, coffee from Brazil, French works of art, etc. Ultimately, however, our credit to Canada is settled by exports to those countries where British goods are needed.

No, the Colonies are wrong in the idea of a self-contained Commonwealth, and Britain is right in her idea of expansion in trade over every part of the world. It is a necessity of our position; without it there can be no stability. The Colonial idea arises from a false notion of what trade is. It will often be observed in the case of the Dominions, and certainly in the case of Australia, that a self-contained colony is not a colony in their meaning in which all efforts are devoted to obtaining the products required for comfortable life from their own soil, but one in which wealth is attained by manufactures and agriculture, from sales made to other nations, and evidently no purchases by them are expected to balance the sales. Indeed, from some statements frequently made, the idea is that an exporter of goods from Australia is patriotic, while an importer is unpatriotic and seeks his own interest regardless of the good of the community. The idea that money is the real or ultimate payment for goods and services seems strongly held by the Colonial mind. England has long ago realised that all goods and services are ultimately paid for in goods. It is not difficult to follow the somewhat infantile reasoning of those who fail to understand the nature of payment between nation and nation. Every manufacturer feels the difficulty of selling. He organises an extensive mechanism of sale, advertisement, travellers, show-rooms for his goods, in many cities in all parts of the world. He sees his goods leave the works and travel all over the world, and the only returns of which he is conscious are the cheques in payment of the goods he sends. He often forgets that money is only a foot-rule for measuring goods and services. It is true that the metals, gold and silver, have an intrinsic value, as wealth, apart from their use as means of measurement; but only a small share of the transactions of the world are accomplished by actual gold and silver payments; the real money payments are by drafts and cheques, which only serve as certificates that certain goods and services have come into existence and are to be balanced against other goods and services. What a nation requires is not money, but material things and services. All that the financial system does is to make possible the exchange of these goods and services within the country and in the external world. Many fail to realise the essential truth that goods and services are only paid for ultimately in goods and services; and further, that the difference between nation and nation is always settled by the import of goods into the creditor country. All real payments, in fact, are in goods and services. Many seem to imagine that the world consists in a series of competing nations, each clamouring to sell but none desiring to buy. War is provoked, according to this notion, by the struggle for markets. It seems to be entirely forgotten that the goods bought in the world are the same as the goods sold; that is, that imports and exports are different names for the same goods. The imports into the nations of the world, so far as the goods are concerned, must be equal to the exports, because they are the same things, called exports at the country of origin and imports at the country of arrival. The analogy of war as applied to commerce is entirely false. Commerce is not a war. Some carry the analogy so far as to imagine a prosperous Great Britain in a poverty-stricken world. People of that type would attempt to render Britain wealthy by making the world poor. They look upon the increase of wealth of the United States with fear and jealousy, and entirely without reason. It will be found, on the most careless examination, that wealth increases simultaneously in industrious nations—a wealthy America means a wealthy England. We must not even forget that a poverty-stricken Germany and Austria would re-act upon the whole world. Punish the Germans and Austrians by all means—they thoroughly deserve it—but do not imagine that by cutting those nations out of

the world's commerce the other nations can be rendered more wealthy. The very opposite is the real effect; in so far as Germany and Austria are poor the rest of the world will share in their poverty. Punishment of these nations should therefore be military, not economic in the sense of rendering production and output difficult. Their war indemnity payments to the Entente Powers must be sufficiently large to reinstate Belgium, France, Serbia, and Russia, and for every ship sunk of the Allies and neutrals a ship must be exacted. Such payments can only be made in material things, and will absorb a very large part of any income which Germany and Austria can make for many years to come. All their powers of production will be required to restore the material damage they have wickedly done.

Notwithstanding the diverse ideals existing within the British Empire, freedom and tolerance allow even antagonistic systems to harmonise. Goodwill between the Mother Country and the Colonies, based upon the belief that Mother Country and Colonies are unselfishly attempting to work out, not only their own salvation, but the salvation of the Empire, permits each to work in its own way, and even in the diversity of method there is a safety to the Empire. Great Britain has by long experience found a mechanism and a method of maintaining her population in considerable comfort. In interesting herself in science, art, literature, and all the things which make life worth living and human mental progress possible, Britain thus contributes her share to the well-being of the Empire first, and second, of the world. The Colonies work out their problems; they learn, find some things possible, others impossible. Any attempt to impose a theory of life or government from the Mother Country would only end in disruption. The experience of America shows us that. This great war, however, sad as it is in loss of splendid lives, is a gain to the Empire. The Kaiser, in his foolishly short-sighted German way, thought to break down the Empire, felt indeed, as one of his professors said, that the giant idol of Britain with feet of clay only required a vigorous push to bring it to the ground. His attempt has had precisely the opposite effect. The struggle with Germany and Austria is a unifying influence, giving every man and woman in the British Empire something to do for a cause deemed just by all. The Empire will be stronger after the war than before. We in Britain shall listen to Mr. Hughes and our Colonial friends who sometimes lecture us upon our misdeeds, with little belief perhaps in those misdeeds, but with an affectionate interest in the speakers, who have no doubt the good of the Empire at heart, and who have shown by their conduct that they stand for an Empire of Truth, Honesty, and Justice. The very liberty and apparent looseness of the bond throughout the British Empire is one of its greatest points of strength. In time each constituent of our great Dominions will work out for itself, in conjunction with the Mother Country, a system best suited to its needs. Each system will gradually be perfected by trial and error, and ultimately the Colonials will recognise that the Mother Country has acted for their good, for Britain's good, and for the good of the world, even when they, from their more restricted view, thought that Britain was following an erroneous ideal.

But the Colonials are by no means alone in calling for drastic change in our methods. Even scientific men consider us to trust too much to haphazard means. The signatories to the Neglect of Science Manifesto, published at the beginning of this year, make the following general statement: "Our success now, and in the difficult time of reorganisation after the war, depends largely on the possession by our leaders and administrators of scientific method and the scientific habit of mind. They must have knowledge and the habit of promptly applying known means to known ends. To trust to luck is a mark of the dangerous complacency bred of ignorance. The evidence of those back from the Front makes it clear that, as of old, our 'people are destroyed for lack of knowledge.'" No doubt people are destroyed for lack of knowledge; but, alas! no man or body of men can give us the knowledge to enable us promptly to apply the known means to known ends, not even the best of scientific men. Except in very simple matters, in order to apply known means to known ends it is necessary to experiment and make numerous trials. The whole work of the scientific man is based upon experiment; even in mechanical matters it is impossible to predict at long range—no new machines or even improvements in machines have been produced by the most intelligent and scientific men without long experimental trials, much less is it possible to predict with certainty the course to be taken in so complicated circumstances as the conflicting interests of a nation.

I agree with my brother scientific men in wishing to secure a more general appreciation of science and scientific men. Certainly science

should be valued more highly in our colleges and schools. But Great Britain has always been rich in scientific discoveries and men of the first rank, and knowledge is rapidly spreading. We have many highly-trained scientific men at present engaged in the application of science to industry. Their success is much greater than many appreciate.

In national affairs there are two ideals of action—one, the rigid logical working out of what are believed to be all possible contingencies and providing for them far in advance. This is the method attempted in Germany. But it requires a being at the head of affairs who is not only all wise but all good and powerful, as the Kaiser supposes himself to be. Had he been so, there would have been no war. The war was due to his and his nation's greed and wickedness, and the systematic obedience of Germany has only made it easier for the mistaken and wicked few at the head of affairs to lead the whole nation downwards to destruction. The British do not believe in the existence of the all-wise or all-good person—the strong man to whom everything is known; they are acutely conscious of the imperfections of human nature, and they are not willing to trust their whole fate to the rulers of the State. On the contrary, they believe with Sir George Paish that "a really clever nation or a really clever man becomes not infrequently a public danger." Sir George's estimate, given as follows, seems to me in the main true: "The British nation has never made the mistake of being too clever. The greatest qualities possessed by the British nation are common-sense and courage combined with lack of imagination. Their foresight is confined to doing the next thing that presents itself. Each difficulty as it arises is dealt with either wisely or unwisely. Their great wealth has been built up by their inability to realise the meaning of the word 'danger,' either from a physical or from a financial standpoint. The British people are prepared to take greater risks than any other people in the world, and this quality has brought to them an income and a degree of well-being that can scarcely be measured."

By thus dealing with each difficulty as it arises, on the whole a better adjustment to the circumstances is obtained than can be effected by the most careful prevision. No doubt mistakes are made, but they are usually mistakes capable of ready rectification. Great Britain thus depends upon the struggles of the democracy. Such struggles may give evidence of much ignorance and error, but the acts which emerge are those which are possible, and are by no means the result of the trusting to luck referred to. Either we must be all wise and good if we are to trust to a scheme carefully planned in advance, or we must trust to the nature of the mass of human beings who form the nation. If that mass be good, capable and honest, then the result in the main will be good. Mr. Asquith and the Coalition Government acted promptly enough when the nature of the circumstances to be faced became visible, but till vision cleared the way they very prudently and rightly practised the "wait and see" attitude which the purely scientific man considers so erroneous.

Contrasting the disasters which have befallen German logical preparation with our rapid growth of strength and power, which is the result of the apparently irregular British method, it must now be evident to all the world that British stability stands firm while German thought has resulted in instability and disaster. I do not for one moment say that the British method is perfect; it can undoubtedly be improved upon, but before any improvement can be attempted it is necessary to admit that on the whole Great Britain has been highly successful. Changes are no doubt necessary, but they are not changes of the order imagined by those who say, like Mr. Hughes, "Never again shall we be caught in the position of the autumn of 1914." Looked at sanely it will be acknowledged that at no time in Britain's history had she been more prepared for the task which she undertook than in August, 1914—the Fleet was ready; the Expeditionary Force was ready. The difficulties, as I pointed out last year, were not on the side of Britain, but on that of our gallant Allies. Since last I had the honour of addressing you a year ago, Britain has made enormous progress in the production of munitions for war, in the development of the aeroplane, improvements in its structure and in its engines, in the design of special means of attack, such as the "Tanks," and numerous other matters, and in the great strengthening of the Fleet and the Army.

The Fleet is overwhelmingly the strongest in the world, and the Army now ranks among the most powerful and well-equipped in the field. The war can now have but one end: the complete collapse of the Central Powers and their allies—Turkey and Bulgaria—and the victory of the Entente Powers—Britain and the Empire, France, Russia, Belgium, Serbia, Rumania, and Japan.

At the termination of this war the British Empire will occupy a position which it has experienced before at the end of a great war, much more powerful in Navy and Army than at the beginning, while her enemies will be weak and at the end of their resources.

What changes then are desirable after war?

There are some points on which all agree. It is necessary to raise the standard of living of the working-classes, although the average income is higher than that of any other European country; yet much more must be done to abolish the poverty which is still too common among the unskilled workers; undoubtedly wages must be raised. How is that to be done? The Socialists used to say that modern machinery and science had increased production to such an extent that the whole error of society lay in the division of the products of industry and not in the actual lack of produce. The capitalistic system of society, they said, enabled the employers to exploit the employed, so that the capitalist reaped the great harvest, leaving only a few poor ears of corn to be gleaned by the workers. The first Census of Production of Great Britain (1907) is an invaluable contribution to our knowledge of the true facts. Broadly, the results are these:—

The total income of the country in 1907 is estimated at 2,000 millions; this is made up of payments for both material things or goods and service of all kinds.

The net output of the scheduled industries of the country is 712 millions; this sum is determined from the goods sold by all the industries at the works prices before any additional expense is incurred by carriage, storage, etc., by deducting from the total output of all the works, the payments made for materials and partly manufactured goods entering the works. The sum, 712 millions, is thus the whole product of the labour of the hands employed rendered possible by the provision of works, machinery, materials from outside, and the invention and design of engineers and men of science. The sum is the source of all payments for labour and capital; and as the total number of workers employed is 6·98 millions, the total earnings of industry per head per annum is £102. If, then, every worker in each factory, masculine and feminine, were paid at the rate of two pounds per week, the whole sum would be exhausted without providing remuneration for capital or a fund for extension of works and development of new inventions or industries.

The value of the agricultural output of the country is 210 millions, and that of fisheries about 12 millions.

The number of people engaged in agriculture is 2,324,000 and in fisheries 107,500; so that the total of those occupied in direct production of goods and food, including employers and salaried persons, is—

Manufactures	8,250,000
Agriculture	2,324,000
Fisheries	107,500
	10,681,500

—that is, 10·681 millions, over 10½ millions.

The total value of the work of those 10½ million people was—

	£
Manufactures	712,000,000
Outwork not scheduled	50,000,000
Agriculture	210,000,000
Fisheries	12,000,000
	£984,000,000

—so that of the whole income of the country of 2,000 millions, under one-half was due to direct production.

Over 1,000 millions in the aggregate was earned by those engaged in transport, distribution, banking, insurance, foreign and Colonial investments, professional services, such as law, medicine, trading, engineering design for abroad, and domestic and personal service. The services for abroad on balance were paid for by 128 millions (the excess of imports over exports in 1907) worth of imported goods and reinvestment in foreign securities, which did not in that year result in sending goods to this country.

The total goods retained for home consumption was thus valued at about 1,100 millions—

	£
Manufactures, agriculture and fisheries, price at works or place of production	984,000,000
Excess of imported goods over exports, price at port of entry into country	128,000,000
	£1,112,000,000

The expenses and profits of transport and distribution, railways, motor and horse traction, water carriage, warehouses, shops, etc., before reaching the consumer amount to about 500 millions, so that the consumer pays for the goods altogether about 1,600 millions. This represents the material remuneration of all producing and distributing and transport and professional and personal services.

The remaining income of 400 millions is that

accruing for services. The total income of 1907 is thus made up broadly—

	£
Material things at place of origin or port of arrival	1,100,000,000
Distribution and transport of those things	500,000,000
Professional and personal services .	400,000,000
Total income of 1907 . .	£2,000,000,000

In 1907 the population of the United Kingdom was 43·7 millions, so that the income per head was £45·8.

The total production of the trades of the country as sold at the works was 762 millions, and if all be divided uniformly, $\frac{762 \text{ millions}}{8{\cdot}25 \text{ millions}}$ = £92·5 per individual engaged in production.

For agriculture and fisheries the total production was 222 millions; similarly divided, $\frac{222 \text{ millions}}{2{\cdot}43 \text{ millions}}$ = £91·4 per individual engaged.

The total net output per head in agriculture thus differs but little from that of the trades.

Out of a population of 43·7 millions, those aged between fifteen years and sixty-five, number about 27·7 millions, of whom 13·3 millions are male and 14·4 millions female. In 1907 we may assume 25 millions to be the reservoir from which we could obtain those actually engaged in the different kinds of work, manufacture, agriculture, fisheries, and services of different kinds. Of those about 11 millions are engaged in manufactures, agriculture, and fisheries, and the remaining 14 millions are occupied in distribution, transport, and professional work. The sum falling to this latter class is about 1,016 millions.

From this examination it will be seen that even if the whole products of the work of all classes be uniformly divided among the individuals, yet it is not possible to increase the remuneration sufficiently per head, because the material things produced are insufficient in quantity. To increase the real income of the country it is absolutely necessary to increase the production of every person. It is useless for scientific men to discover, and engineers to invent, new means and mechanism for producing from the earth the things we require for comfort unless the workmen be willing to use these means and machines to the best advantage. The best thing we can do at present for the future prosperity of the country is to convince the workman that it is in his interest to increase production to the utmost consistent with healthy life, and to show him that, in so doing, he increases the supply of materials available for the purposes of necessity and comfort which are brought into existence to be divided among the whole population.

Unfortunately many workmen and some trade unions conceive it to be their interest to restrict production, partly from the idea of keeping up prices by relative scarcity, and partly from a very kindly feeling that if any man does too much work he is robbing his neighbour workman of a job. He thinks that there are only a certain number of jobs to go round, and he does not wish to be selfish and throw other men out of employment. That is a completely erroneous view; it is in the interest of every workman in the kingdom to increase his production to the utmost. Many employers have, however, helped to confirm the workman in his error by a too narrow view of the limits of men's wages. After a fair piecework price has been settled, they do not allow the man to increase his earnings sufficiently by thought and industry. If his piecework earnings rise, say, to £5 per week, they consider the rate too high and seek to reduce it so that his wage shall be kept not higher, perhaps, than £3. This is an unjust and incorrect policy; workmen should not be so limited, or they will consider it to their interest to limit their production. Every inducement should be given to the workman to earn the largest sums, provided the price of each article is a fair one which can be borne by the selling price available. Both workmen and masters should alter their ideal in this respect. Trade unions have done excellent work for Great Britain in raising the standard of life of the workman, and we all sympathise with them in this. The higher the average standard of life in the country the better is both the internal and external trade of the country; but the trade unions should devote themselves to raise income by facilitating production and seeing to it that the workman is paid at proper piecework rates.

It is a remarkable fact that the United States of America, with its 100 millions of population, is adequately served as to its industrial needs by 8·85 millions of workers, while we require 8·24 millions to supply the needs of 43·7 millions. The American net output per head is about £220 for manufactures and £206 for mining. The net agricultural output is enormous; it is 1,100 millions for crops alone without live-stock. It is true that prices are higher in the United States of America than here, and so the output is magnified by the less goods obtained for a given sum; the prices, however, are believed

to average about one and a half times those in this country, so that if we divide £220 by 1·5 we get near £147 per head as the true equivalent of the £102 per head of the British Census.

It is to be noted, however, that the net output of the German workman is much lower than that of the British. We shall be nearly accurate if we say that the American worker in industry turns out one and a half times the real value of the British workman. This he is enabled to do by the difference in ideals of labour between the trade unions of the two nations. The American unions recognise that a large output is necessary, and they devote their energies to maintaining the high wages of the worker by keeping up the piecework prices, and accordingly we find that the total wages paid in American manufacturing amounted in 1909 to £687,000,000, or over £100* per annum per head; the wages formed 40 per cent. of the net output—and so, notwithstanding the dearer living, the people are on the whole better paid than here. It is not possible to say that they are really better off, as their hours are longer—sixty hours per week, no Saturday half holiday; while in Great Britain fifty-four hours form the standard week, and the Saturday half holiday is almost universal. An increase of the output of British manufactures to the extent of 50 per cent. by greater utilisation of automatic machinery would produce a very great improvement of our prosperity as a whole without increasing the working hours; but more especially it would act to raise the level of living of our wage-earning classes. The home trade would thus be greatly strengthened, and with it the foreign trade would improve also. There can be no effective demand for goods from a poor population, and wealth consists fundamentally in the total material production. Services are only of national value in so far as they are instrumental in producing and distributing actual things such as food, clothing, housing, and some services are necessary in order to keep us in bodily health and to maintain society in an orderly state in which all of us may enjoy the results of our labour. The improvement in the output of existing labour is therefore of vital importance. This, however, can be aided by opening numerous fields of activity to women. Women have shown themselves most capable and eagerly patriotic in the years of the war; they have had a chance to show what they can do, and they have abundantly demonstrated their skill and adaptability to new and strenuous conditions. Their skill, goodness and bravery is beyond all praise.

The future prosperous Britain will certainly arrange to utilise to the utmost women's work in many industries, both manufacturing and distributive; such a fund of energy and ability cannot fail to improve the income of the country. The workman need not fear competition; there is ample work for women, both in the trades and in the professions. Women will also be given their rightful position as fellow councillors with men in determining the course and affairs of the nation.

Our first aim at home, then, should be to increase the total of our material goods by improving the ideal both of labour and capital, and by encouraging women to take part in industry and the professions. Give women a fair field in outdoor life as well as in the life of the home.

Our next aim should be to impress upon the Dominions overseas the one great necessity for their healthy existence—a larger population. The late Professor Seely, in his "Expansion of England," predicted a combined British and Colonial population of 100 millions of Anglo-Saxon race for the year 1930. So far the Mother Country has succeeded, and the population of these islands is over 46 millions. That of the overseas Dominions, including Crown Colonies and Protectorates, is only 16 millions. Here we cannot expect to support in real comfort more than 50 millions of people, but with the huge area of Canada, Australia and New Zealand, they should between them easily maintain 50 million in a high degree of comfort and leave plenty of room for expansion. We should then have a British Empire with 100 million souls mainly of our own race—English, Scottish and Irish. Such a population would increase, not diminish, the wealth of every individual, and would greatly

* Notwithstanding the larger average income of the American workman, there seem to be conditions which give rise to much discontent. This is frankly expressed in an article in the *Engineering Magazine*, of September, 1915, by Mr. David Moffat Myers, M.A.S.M.E., a well-known American engineer. His statement is—

"In our factories all over those freedom-loving States of ours, there are thousands on thousands of human slaves—white slaves. 'The factory runs the town.' You know it as well as I do. You know these slaves. You are sorry for them, with their long, hard hours, their insufficient pay, their absolute lack of freedom. And these people, these human beings, constitute ninety per cent. of the people connected with your factory which pays dividends to the ten per cent. But what of the ninety? Has the factory improved their lives? Has it given them luxury, freedom, cultivation, and happiness? Has it improved their citizenship? No need to answer these questions. Everybody knows—when he stops to think.

increase the strength and importance of our overseas Dominions.

The present small populations of the Dominions is detrimental to their industrial prosperity; for example, the populations and income in 1914 stood as follows :—

	Population.	Total Income.	Income per Head.
		£	£
Canada	8,075,000	350,000,000	43·3
Australia	4,922,000	230,000,000	46·7

They have not yet attained to the £52 per head of the United Kingdom. They should in time equal, and even exceed, the wealth of the home country, because of their large area and wealth in coal, minerals and grain in Canada, and in minerals and cattle in Australia. To do this they must of themselves discover that the ideal of a "self-contained Commonwealth within a self-contained Empire" can lead them no further, and that it accounts for the relatively small progress they have made in power and importance compared to that of the United Kingdom. The world, after all, is but a small unit, and Colonial ideas as to industry and trade should expand in a more ambitious way so as to utilise the advantages of the whole range of products and services which our little sphere affords. Vigorous and able people such as the Canadians, Australians and New Zealanders should content themselves with no ideal of activity less than worldwide. I do not refer to warlike activity, but to the ordinary desires of mankind to live a life worth living in a peaceful way, so arranging that each individual's work benefits him or her and aims to benefit the world as well.

So far I have discussed things material rather than those intellectual, because Science, Art, Literature, and all other abstract matters require a country which is on the whole prosperous; the intellect cannot flourish in a poverty-stricken nation. All intellectual matters are of the utmost importance to the race; the highest interest of man is found in the development of the intellect; it is there that the consciousness of man differentiates him from the animals. Accordingly Great Britain would do well to improve the education of her people in order to give them a happier and more worthy life. Our knowledge of objective things is, after all, purely subjective, and our belief in the existence of objects external to ourselves gives a vivid interest to the pursuit of knowledge of the real things which we feel exist behind the veil of subjective sensations and impressions. The knowledge called scientific is, after all, but knowledge of the sequences of occurrences as observed through our senses and imagined by our consciousness. We observe many complicated happenings, and we classify them, referring them to divisions which we have created to enable our thinking powers to grasp something tangible; accordingly we divide Science into Biological and Physical. In each division we arrange apparently differing phenomena in one class, because of a common property, and we determine the quantitative laws of the various relationships. Such work gives us the highest pleasure, as an attempt to learn something of our wonderful world, and in this men who devote their lives to the most abstract of natural studies do noble service to all mankind, because they aid the development of human brain-power, so that in the distant future we may be able to achieve a real understanding of the simplest of things around us—a stage which we have not yet reached. The work of Science, Art, and Literature is all of a high order, and Science to its votaries is satisfying in itself as an ultimate aim; the scientific discoverer pursues his inquiry into the phenomena of matter and life with knowledge as an end in itself.

The increase of such abstract knowledge is necessary to Great Britain's stability; and, judging from the past and present, we shall never lack men who devote their lives to the pursuit of knowledge, so satisfying in itself and so vital to the continued conquest of Nature by man.

It is necessary, however, that we should as a nation recognise more fully the importance of co-operation and co-ordination in both abstract and applied science. We are intense individualists, and our great success in the world is largely due to that quality; it has, however, its drawbacks, and we have arrived at a stage of development in both science and industry where united effort would aid us rapidly to improve our scientific and industrial position. I accordingly welcome the movement of Co-ordination of Scientific Societies originated by the Royal Society and the establishment of the Privy Council Committee for Industrial and Scientific Research by the Government. Great technical and industrial progress will result from the joint action of those bodies with groups of the great industries on which our comfort and security depend.

The joint work of the Advisory Committee for Aeronautics, the National Physical Laboratory, and the Royal Aircraft Factory for years past is proved to be eminently successful by the dominant position of our aeroplanes at the Front. Without this joint action it would have been impossible for us now to maintain our leading position, and it would be well for us to place work of this kind on a sound financial basis.

Although most of our scientific and industrial progress has been achieved by individual concentration, yet there are many problems of the utmost importance to the nation and the Empire which can only be solved by national effort. I view, therefore, with much pleasure the growing appreciation of science and industry shown in this time of war by H.M. the King and the members of our Government. Professor Unwin, in a recent able and stimulating address, quotes the well-known remark of Bagehot, made many years ago :—

"We English are always grumbling at ourselves. But, after all, England is a success in the world; her career has had many faults, but it has been a fine and winning career on the whole."

I would plead with our "professional whimperers" to take a more cheerful and just view of the achievement and stability of our common country, and to moderate their gloomy joy in depreciation.

Even Germans have had occasion to change their views of England. In a recent issue of a Munich paper it is stated :—

"France, though bleeding from a hundred wounds, will not give way one inch. Russia, which has been declared exhausted so often, is silently stamping ever new million armies out of the ground. England, which wields its old dominion of the seas more powerfully than ever, has taken up the fight on land against us with incredible energy and self-sacrifice. Against us stand not only colossal material, but immense intellectual and moral forces."

So the Germans are awakening to a consciousness of the futility of their dream of domination founded upon the idea of might irrespective of the rights of other nations, and they will ultimately be forced to accept the idea so strange to them hitherto that honesty between nation and nation is as necessary as between man and man.

Britain's stability in the future as in the past will flow from continued honesty and fair play, and her material success from consideration of the interests of the whole world as well as her own.

APPENDIX.

EXTRACTS FROM PAPER ON "BRITISH AND GERMAN EXPORT TRADE BEFORE THE WAR."

By H. H. O'Farrell.

From "The Economic Journal," June, 1916.

. . . . It is proposed in the present paper to deal only with the exports of the United Kingdom and of Germany between the years 1895 and 1913—the last year for which we possess complete information as to Germany's foreign trade.

This period of nineteen years may conveniently be grouped into averages of four periods—three of five and one of four years. The first figures to be noticed are those of the total foreign trade (exclusive of bullion), which are as follows :—

Total Exports (Millions of £).

	Average of 1895–99	1900–04	1905–09	1910–13
United Kingdom .	300·0	356·6	462·5	581·2
Germany	197·9	251·8	340·1	460·0
Balance in favour of United Kingdom .	102·1	104·8	122·4	121·2

These figures, as well as those to be subsequently given, do not include the exports of the United Kingdom to Germany, or *vice versâ*. The direct trade between the two countries has been excluded in order to deal only with competition in foreign markets. The preponderance of British exports in the first period is really slightly greater than appears above, since the export of new ships was first included in the British statistics in the year 1899, while it found a place in the German figures two years earlier. . . .

The figures of the total trade of both countries give due weight to the re-exports, which form one of our most considerable commercial assets, and their transport is really as much a domestic industry as any other. Lacking this item, the "special exports," or exports of the domestic produce of the United Kingdom, appear in a less favourable light in comparison with those of Germany.

SPECIAL (DOMESTIC PRODUCE) EXPORTS (MILLIONS OF £).

	Average of			
	1895-99	1900-04	1905-09	1910-13
United Kingdom	239·6	289·2	377·4	474·2
Germany	181·3	235·6	314·2	425·7
Balance in favour of United Kingdom	58·3	53·6	63·2	48·5

So far, the results appear to indicate that, while our total exports have been pretty well maintained throughout, there has been a not inconsiderable falling behind in the case of the purely domestic exports in the last of the four periods. It is to be observed, however, that this is not due to any slackness on our own part—for the increase of British exports is more than maintained throughout—but to a special spurt which our rival appears to have made in the four years preceding the war. In the last year the German imports, which had reached a figure of over 525 millions in 1912, were nearly stationary at 529 millions, but the exports increased by more than 40 millions; the imports of bullion increased by 110 millions, and the exports of bullion decreased by about 40 millions. It may be safely conjectured, I think, that the activities of the last four years were not purely commercial.

In any case it is not sufficient to look at the figures in the lump merely. It is necessary to dissect them in order to ascertain their real significance. The first great division into which they fall is into the trade with European and non-European countries respectively. Russia will be included in the first and Turkey in the second group. Taking the European countries first, we find the figures to be as follows:—

SPECIAL (DOMESTIC PRODUCE) EXPORTS TO EUROPEAN COUNTRIES (MILLIONS OF £).

	Average of			
	1895-99	1900-04	1905-09	1910-13
United Kingdom	64·5	76·2	97·4	121·6
Germany	100·3	128·7	179·6	255·9
Balance against the United Kingdom	35·8	52·5	82·2	134·3

The superiority and uniform progress of Germany as regards the trade with European countries is clearly indisputable.

On the other hand, when we look to the trade with the rest of the world outside the Continent of Europe, we shall find a still more remarkable superiority on the side of the United Kingdom. The figures are as follows:—

SPECIAL (DOMESTIC PRODUCE) EXPORTS TO NON-EUROPEAN COUNTRIES (MILLIONS OF £).

	Average of			
	1895-99	1900-04	1905-09	1910-13
United Kingdom	152·6	188·4	246·0	313·3
Germany	45·3	60·7	83·5	110·4
Balance in favour of United Kingdom	107·3	127·7	162·5	202·9

The broad conclusion to be drawn from these figures would seem to be that, as regards the Continent of Europe, Germany had a great superiority, obviously due to her central position and to her magnificent railway and water communications with the countries by which she is surrounded; while we, on the other hand, had an even greater advantage as regards the rest of the globe in our ocean communications and in the increasing magnitude and efficiency of our mercantile marine. The Continent, in the pre-war days, was becoming more and more the *hinterland* of the German railways, while the overseas countries of the world remained in increasing measure the sphere of influence of British sea supremacy. The contest has been between land carriage and carriage by sea, each exploiting the field most favourable to its activities. . . .

Another point which is noteworthy is that the trade of both countries increased *pari passu* throughout the period, and that neither seems on the whole to have gained at the expense of the other. Germany did not, so far as the figures disclose, oust us from any trade that we possessed before, nor we Germany. Out of an increasing volume of trade Germany obtained the major portion of the excess in Europe, Great Britain in the rest of the world. With the exception of certain years just after the South African War, and the two years of the American crisis and its aftermath (1908–09), there is no instance of a positive decline in British exports synchronising with a contrary movement in German exports. This is the more remarkable considering the strenuous efforts which Germany is well known to have been making to extend her foreign trade. . . .

With the exception of the United States and Mexico, where Germany competes with us on approximately equal terms, there appears to be no non-European country in which British exports are not considerably in excess of German. The preponderance is accentuated in the case of our overseas possessions and Dominions, but is by no means confined to them. . . .

On the whole, the figures we have now passed in review are by no means discouraging, and it must be remembered that they reveal nothing of the quality of the trades compared. British commerce, it may safely be assumed, is always carried on with a view to more or less immediate profit. There is reason to suspect, on the other hand, that much German trade has been merely the seed-corn of a speculative harvest, destined, it may be hoped, never to mature. But, taking the figures at their face value, the result would seem to be to dispel exaggerated notions of German competition. Great as German progress has been in the past, British progress has been greater. There is unquestionably much room for improvement; for better organisation, for more businesslike methods, for

a larger appreciation and a more liberal endowment of research; but the vision of an all-conquering Germany has not been true in the past, and assuredly should be even less possible in the future.

After delivering the address, the Chairman presented the Society's medals, which were awarded for papers read during last Session.

At the Ordinary Meetings:—

J. Arthur Hutton, "The Effects of the War on Cotton-Growing in the British Empire."

George Percival Baker, "East Indian Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

In the Indian Section:—

James MacKenna, M.A., I.C.S., "Scientific Agriculture in Europe."

In the Colonial Section:—

Sir Sydney Olivier, K.C.M.G., "Recent Developments in Jamaica: Internal and External."

Sir Robert A. Hadfield, F.R.S., in proposing a cordial vote of thanks to the Chairman for his address, said he had never heard a more lucid, more clear and better expressed discourse. The subject with which it dealt was a very wide one, but those present would be able to take away with them a broad and comprehensive view of the future of this great country. Personally he was thankful to say he was an optimist; like the Chairman, he had never felt that this country would not be able to hold its own in the future. If the people were true to themselves, the nation would continue to expand and have a bigger share in the concerns of the world even than they had had in the past. The Chairman had alluded, among other things, to the interesting question of hours of labour. Personally he hoped that some day a forty-eight hours' week would be established. Speakers often expressed an opinion from theoretical considerations, but he was able to speak from something like twenty years' experience in his works in the north of England, where forty-eight hours a week had been worked with, he was thankful to say, great success. The subject was very much in the air at the present time, and he thought a forty-eight hours' week had come to stay permanently. He specially referred to the subject because he thought it was the duty of the employer to convince the employee that he had his interests at heart. It was an old-fashioned principle to expect an ordinary human being, brought up under modern developments, to be at work before six o'clock in the morning. His own workmen came after they had had breakfast, and he was quite confident that much better work was obtained from them as a result of that little privilege, which was highly esteemed. He was very glad the Chairman had referred to the admirable paper by Mr. O'Farrell. It was very unfortunate that the excellent papers read before the Statistical Society, about whose work sufficient was not known, were not brought more generally before the notice of the members of the public.

Sir George R. Askwith, K.C.B., K.C., D.C.L., in seconding the motion, said that, like the mover of the vote, he was on the optimistic side. In the course of his address, the Chairman had alluded to the fact that after the war wages should be raised, and secondly, in order to get that increase of wages, there must be an increase of production. It had been his duty, during the last two and a half years, to deal with very large increases of wages, amounting in nominal value to millions upon millions of pounds, and affecting hundreds of thousands of human beings. At the beginning of the war it was feared that in certain sections of trade there might be a great amount of unemployment and a great loss of wages. That fear had not come true, but it was some time before the doubt was dispelled. It was possible that at the end of the war a period of doubt, hesitation, and adjustment might again ensue; but after that, and even during it, he looked forward to a period of production, and of the necessary reinforcement of the waste that had taken place, which would lead to an increase of, or at any rate the maintenance of, wages, and the desire to maintain those wages would also lead to an increase of production. It had been a very bitter thing indeed for many trade unions to give up rules, regulations, and ideas that they had been working for for a quarter of a century or more, but some of them in a surprising manner had adjusted those rules and regulations, and where they had done so upon right lines the result had been to the satisfaction of most of the individuals who composed them; and he doubted whether some of them would ever go back to the policies and to the rules which existed before the war. The Chairman had also referred to the importance of women taking a part in various branches of industry. That, it was obvious, would be practically a necessity for this country, but if the women were to go into industry other than that connected with munitions, where wages were at present high, it would be necessary for the employers in different branches of industry to realise that they were not likely to be drawn to them unless the wages were made sufficiently attractive to induce them to give up a life of idleness or withdraw from pursuits that they liked better. The Chairman had mentioned that this country had gained a great deal of its power by waiting until it was seen what the facts were, and the circumstances became visible. He hoped the "wait and see" policy would not be carried too far, because it was a dangerous thing to "wait and see" too long, until the nation went to sleep, did not realise what the circumstances were, and did not provide in time for them. It was necessary to look forward and to organise, and then he thought this country would maintain the great position it had already achieved, and rise even to a higher plane.

The resolution of thanks was put to the meeting by SIR ROBERT HADFIELD and carried unanimously.

THE CHAIRMAN, in thanking the mover and seconder for their appreciative words, and the members for the heartiness with which they had received them, said he quite agreed with Sir George Askwith that they must not "wait and see" too long.

The meeting then terminated.

ENGINEERING NOTES.

The Oil Shales of Norfolk.—Mr. W. Forbes-Leslie recently read a paper on the above important and opportune subject at the Institution of Petroleum Technologists, in which he discussed, among many interesting facts regarding the geological parts of the question, the matter of the origin, especially as to the Puny Drain geological series. The organic contents of the shale common to that formation are remarkably constant in amount throughout the series, both along the outcrop and on the dip. The oil in the Puny Drain shales appears to be derived from two different sources—first from indigenous material, possibly of animal origin, and, secondly, from a source of free oil. Whether this is formed *in situ* as the result of the natural distillation of more deeply-seated shale beds and the rise of the resulting volatile products into the superficial and superincumbent beds, which are now exposed, or whether, as seems more probable, it comes from a source of liquid oil confined at a high pressure beneath the series, it is not yet possible to demonstrate. That free oil does exist is clearly shown by three classes of evidence: First, as much as 1 per cent. of oil is dissolved when the shale is treated with ether; second, from the prospecting side, when the limestone capping is penetrated, water covered with oil appears in the sinking, or when a piece of shale recently broken out from the bed is subjected to running water the oil is seen to escape and form a scum on the surface; and third, when the shale is treated in retorts it is found that the greater part of its oil contents comes off at a temperature under 300° C. The oil obtained from both series of shales is golden black in colour, with a purplish tint in reflected lights. It is very fluid, running almost like water, despite the fact that its specific gravity is as high as ·942 to ·960. In this respect it differs from the Scotch shale oil, which is dark green in colour, with a specific gravity of ·860 to ·890, and very viscous, with a settling point of about 32° C. Norfolk shale oil differs likewise from oil derived from the Dorset-Kimmeridge series, both in colour and in viscosity. The specific gravity of the motor spirit of petrol obtained from redistillation of the oil is ·855, with a low flash-point; Scotch shale naphtha has a specific gravity of ·734. Bulk tests carried out on Puny Drain shales, both in the field works erected near the outcrop and in works under the supervision of engineers appointed by financial interests, gave highly satisfactory results. The yield of oil on a commercial basis was 40 gallons to the ton, the nitrogen content was about 1 per cent., and the yield of sulphate of ammonia was 66 lb. per ton; while there was obtained 25,000 cubic feet per ton of dry gas possessing highly illuminating properties. Sulphur contents were as high as 6·4 per cent. The oil obtained on these bulk tests had a high specific gravity, namely, ·942 to ·960, and was very fluid. The yield of fractions coming within the limits of the motor spirit series is considerable. In addition, the oil yields from 3 to 4 per cent. of bases extracted by weak acids, 3 to 4 per cent. of crude phenols, cresols, etc., and 3 to 4 per cent. of benzol and toluol. The main interest of these bulk trials is the extremely low temperature at which the shales yield a big proportion of their oil contents, and that the residues contain 20 to 27 per cent. of carbon, fixed and unfixed. The quantity of the sulphur contents varies from 4·32 to 7·8 per cent. Here the shale conforms to the known sulphur contents of the Kimmeridge series generally. Mr. Forbes-Leslie points out that much has been made of the sulphur difficulty, and gives many instances showing its practical unimportance.

Equipment for Thawing Frozen Pipes.—A thawing outfit, put into service lately, has enabled the St. Paul, Minnesota, Waterworks Department to thaw out any frozen water service on which it has been tried within a maximum of fifteen minutes. The apparatus consists of a gasoline engine direct-connected to a generator, a switchboard and a reel of cable, the whole mounted on a structural steel frame, so that it can be handled as a unit. The four-cycle, four-cylinder gasoline engine, built by the Capitol Engine Works, St. Paul, is direct-connected by a leather-link flexible coupling to a Roth Brothers 20 kw. 40-volt direct-current generator. A voltmeter, an ammeter, a rheostat and a single-pole knife switch of 500 ampere capacity are mounted on the switchboard. The reel holds 500 ft. of extra flexible copper cable of 300,000 circ. mils cross-section, in 100-ft. lengths. Each length is fitted with terminal lugs. The various parts of the equipment are securely attached to the steel frame, making the equipment easily portable. For service the equipment is mounted on a Troy trailer of 1½ ton capacity, which is hauled about by a motor truck. The mounting is not permanent, and after the winter season the thawing unit will be removed and the trailer used for other purposes. To thaw out a service one pole of the generator is connected, in the premises, to the pipe between the meter and the street main.

The other pole is connected with the nearest fire hydrant. Thawing is effected in from five to fifteen minutes after the current is turned on.

The South African Ports.—The South African Government, which have the whole of the ports under their charge, give the following account of their works. The harbour at Cape Town consists of a large outer dock, 67 acres in area, known as the Victoria Basin, and a smaller dock of 8½ acres. As the result of dredging operations now in hand with the Victoria Basin, it is hoped to increase the average depth of the dock to 36½ft. The authorities have under consideration the adoption of a comprehensive scheme, estimated to cost £3,000,000, which makes provision for eight large additional berths, with a depth of water alongside of 40 ft., and able, therefore, to accommodate vessels of the largest size. The want of adequate ship-repairing facilities at Cape Town is partly redressed by the arrangement whereby the large Admiralty dry dock at Simonstown may be used for commercial work. The gradual conversion of Port Natal into a first-class harbour represents an engineering triumph over great difficulties. In 1902 the average low water depth over the entrance bar was between 18 ft. and 19 ft.; it is now nearly 36 ft., and alongside the wharves on the Point, the shipping area of the harbour, the depth of water at low-water spring ranges from 22 ft. to 38 ft. 6 in. At the bunkering station on the Bluff considerable extensions have been made to the loading plant, and electrically-operated belt conveyors are now being installed to bring the facilities in line with the most modern practice. At the Congelle Wharf site great developments are foreshadowed, including an important reclamation with the object of extending the wharfage accommodation, providing industrial sites, and attracting new branches of manufacture. The facilities for both the export and the import trades have been admirably planned, and the years immediately following the war are expected to be a period of considerable commercial expansion at Durban. Algoa Bay, from the fact that it can be made and entered in all weather, is the refuge harbour of South and East Africa. It is not a bunkering port, but has good accommodation otherwise, and enjoys excellent railway facilities. The port of East London, commonly known as Buffalo, has recently made good progress. At the present time an important scheme of improvement is being carried out. The work in hand includes the construction of nearly 3,000 ft. of new concrete breakwater, the deepening of the entrance channel, and the provision of deeper water alongside quays. Until a comparatively recent date the principal shipping centre was on the east bank of the river, but the west bank is now becoming the chief shipping area. The west quay, which has been completed only recently, is a solid stone and concrete structure over 1,000 ft. in length. At Mossel Bay a reinforced concrete jetty has been recently constructed for the accommodation of passenger traffic. The jetty, which is 500 ft. long and 60 ft. wide, is protected by a breakwater 320 ft. long, which has been built out from a stone wharf constructed on reclaimed land on the eastern side of the new jetty. The total capital expenditure on the five ports has been in excess of £10,000,000. The *Times* is our authority for these details.

The Winnipeg River, Canada, and its Resources.—A report on "The Winnipeg River Power and Storage Investigations," by Mr. J. T. Johnston, was recently issued by the Water Power Branch of the Canadian Department of the Interior. The report, of which the following is an abstract, shows that power is now being produced at two of the nine possible power sites which exist on the Winnipeg River within the province of Manitoba. The older installation of the two is that of the Winnipeg Electric Street Railway Co., and is situated about fifty-eight miles in a direct line from the city of Winnipeg on the Pinawa Channel, into which a portion of the flow of the main river is directed by means of diversion weirs. The plant, which was practically completed in 1906, comprises nine main turbines, each connected direct to a 2,300 volts three-phase generator. For transmission to Winnipeg the voltage is transformed up to 60,000 volts, and the power developed amounts to about 28,000 h.p. The second installation is that of the city of Winnipeg at Point du Bois, where the first section of plant, completed in 1913, consists of five main units, each coupled to a 3,000 k.v.a. generator. In 1914 three larger turbines were erected, each coupled to a 5,000 k.v.a. generator, and producing, like the older machines, three-phase current of 6,600 volts, 60 cycles, which is transformed up to 66,000 volts for transmission to Winnipeg, seventy-five miles distant in a direct line. These eight machines yield about 25,000 h.p., but with extensions a maximum of 77,000 h.p. can be obtained. Thus at present about 53,000 h.p. (expressed in terms of 24 hour h.p at 75 per cent. efficiency) is being obtained from the river and transmitted for use in and around the city of Winnipeg. This amount is only about one-eighth of that which, according to the report, could be obtained were the other seven sites fully exploited and the river regulated, as is thought quite feasible, to maintain a minimum flow of 20,000 cubic feet per second in the power reach in Manitoba. If the latter condition were fulfilled the total that could be developed is put at 418,500 h.p., but even with the present minimum unregulated flow of 12,000 sec. ft. nearly 250,000 h.p. could be obtained. There

are seven sites enumerated in the report. To a large extent the river is composed of deep, broad basins with, but little current, broken by abrupt changes in level at the various falls and rapids. The drops are generally well concentrated and the hydraulic gradient between them usually negligible, and this combination of circumstances renders possible the utilisation for power purposes of practically the whole fall of the river. The reach below the Lower Seven Sisters and the Pinawa Channel are the only sections in which it has been necessary to sacrifice any considerable portion of the drop. The total capital cost of developing these seven sites, the power being placed on the low-tension switchboard in the power stations, is put at £2,664,000, with a 12,000 sec. ft. flow, and at £4,909,000 with a 20,000 sec. ft. flow. The corresponding annual working costs are estimated at £258,000 and £483,000, equivalent to a mean, based on the power output, of 0·065*d.* and 0·059*d.* per kw. hour with 100 per cent. load factor, and of 0·13*d.* and 0·118*d.* per kw. hour with 50 per cent. load factor. The first power undertaking to acquire rights and begin construction operations on the river since the organisation of the power survey is the Winnipeg River Power Company, controlled by the same interests as the Winnipeg Electric Railway Company, which has arranged to exploit the Du Bonnet site under the name of the Great Falls Development. It offers an excellent illustration of the manner in which the interests of the investor and of the public are served by a careful and thorough investigation of a river's power resources and by a predetermined scheme of power development conserving fully all the head capable of economical development. The surveys carried out by the department enabled the company to take immediate action for the construction of the station as soon as authority was received, without the necessity of carrying on long and expensive preliminary surveys, while the interests of the public were served by the preservation of a profitable power site at the McArthur Falls, which under the first proposals of the company would have been rendered uneconomical of development. The provisional plans of the power station at Great Falls provide for the ultimate utilisation of the whole of the regulated flow of the river, by means of eight 21,000 h.p. turbines, each running at a speed of 163·3 revolutions per minute and requiring 4,100 cubic feet of water a second under a head of 56 ft. These will drive eight electric generators, each having a normal rating of 11,000 kw. at 30° C. (86° F.) with a continuous overload capacity of 50 per cent. These machines will generate three-phase current at 12,000 volts, 60 cycles, which for transmission to Winnipeg will be transformed up to 110,000 volts by means of five banks of transformers, each consisting of three single-phase transformers. In the first instance, four complete generating units are to be installed, but the hydraulic works, including dams, sluices, building, gates, etc., will be so far completed that any of the four remaining units may be put in place without further construction work beyond that required for their actual installation.

OBITUARY.

Sir Walter Vaughan Morgan, Bt.—Alderman Sir Walter Vaughan Morgan died on the 12th inst. at his residence in Whitehall Court.

He was educated at Christ's Hospital, and on leaving school he obtained an appointment in the National Provincial Bank of England, and by the age of twenty was a chief cashier in their Manchester branch. In 1855 he left the bank to join five of his brothers in business in the City of London. They founded the Morgan Crucible Works at Battersea, and established two trade journals, the *Ironmonger* and the *Chemist and Druggist.*

Sir Walter's municipal career began in 1892, when he was elected Alderman of Cordwainer Ward. In 1900–1 he served the office of Sheriff, and in 1905, when he was seventy-four years of age, he was chosen as Lord Mayor. At the close of his Mayoralty he was created a baronet, and he also received the insignia of high grades in the Legion of Honour and other foreign Orders. He was a great traveller and a man of wide benevolence and charity, and he and his brothers devoted a considerable portion of their large incomes to purposes of philanthropy.

He was elected a member of the Royal Society of Arts in 1889.

GENERAL NOTES.

Board of Education Examinations in Science and Technology.—The Board announce that no Lower General Examinations will be held in 1917, but they hope to be able to hold the Higher General Examinations in that year, and they would be conducted in accordance with the regulations and syllabuses which governed the conduct of those Examinations in 1915 and 1916. Should it, however, prove necessary at a later date to suspend the Examinations, the Board will endeavour to give as long notice of the change as possible. After 1917 no Higher General Examinations will be held in Pure Mathematics, Theoretical Mechanics (Solids), Theoretical Mechanics (Fluids), Heat, Magnetism and Electricity, Organic Chemistry, Coal Mining and Metallurgy. The conditions governing the award of Scholarships, Exhibitions, etc., in Science in 1917 are being announced separately.

Estimated Yield of Hops in England.—A preliminary statement recently issued by the Board of Agriculture and Fisheries, estimates the total production of hops in England in 1916 at 307,844 cwt., as against 254,609 cwt. in 1915. The area under cultivation as returned on June 4th in 1916 and 1915 was 31,352 and 34,744 acres respectively. The estimated average yield per acre this year, viz., nearly 10 cwt., is about 2¼ cwt. above that of 1915, and ¾ cwt. above the ten years' mean.

Vegetable Dyes.—The value of logwood at the present time is well realised, but unfortunately, says the *Colonial Journal*, it takes a long time to produce it. The price was good in the nineties of last century, but declined so much that cultivation was largely abandoned. The trees are easily planted, and Jamaica, the Leeward and the Windward Islands are very suitable. The price before the war was £2 10*s*. to £3 per ton, and has risen to £8 10*s*. Imports into the United Kingdom have recently been below those of 1910 and 1911. Jamaica chiefly sends logwood extract, of which the value in 1914 was £172,582. Fustic, from which a yellow dye is obtained, also thrives in the West Indies, and annatto and turmeric are frequently grown. Possibly the efforts which are being made in this country to increase the supply of dyes will lead to greater demands for these products, but it has to be established that really satisfactory results can be obtained from them before they can permanently displace aniline dyes.

German East Africa.—There is a good deal of difference of opinion as to the commercial value of German East Africa. There is much rather poor land, says the *Colonial Journal*, but in so great an area this is not very material, as there is abundance of first-class country, both for agriculture and for stock. The comparison with our own territory should be as to the use which has been made of the land. Thus, sisal has been a remarkable success in the German territory, but this was largely owing to the fact that the Germans produced the best decorticating machinery. The highlands there are lower than our own, but the altitudes of British East Africa are responsible for so many cases of nervous disturbance that this may not be a disadvantage. An important point is the supply of labour, and this is reputed to be more plentiful and better in the German colony. Migration from the south will naturally tend to stop there if it finds the British flag in possession, and in time the Boer settlement would receive substantial additions. German East Africa has become a very important producer of fibre. In 1915 it exported in sisal fibre alone a value of £750,000, and the production was growing at a very rapid rate. No British colony produces fibre suitable for making twine except New Zealand, which only furnishes 20,000 to 30,000 tons out of 250,000 tons which the world requires. Most fibre is produced in Mexico and the Philippines, but German East Africa was fast becoming a valuable source of supply of this necessary product. Very little sisal fibre is used in this country, but London merchants bought largely from Hamburg, and sold to the bindery twine manufacturers in the United States.

MEETINGS FOR THE ENSUING WEEK.

Monday, November 20...Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Address by the President, Dr. C. Carpenter, on "Chemistry and Engineering."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. and Mrs. W. S. Routledge, "Easter Island."

Tuesday, November 21...Swiney Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture IV.)

Petroleum Technologists, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Messrs. E. L. Lomax, A. E. Dunstan, and F. B. Thole, "The Pyrogenesis of Hydrocarbons."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. J. J. Ball, "Keadby Bridge."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Dr. G. H. Rodman, "On Pollens and the Fertilization of Flowers."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mr. A. Ezra, "Lantern Exhibition illustrating a Hunting Trip in Central Asia." 2. Professor B. Petronievics and Dr. A. S. Woodward, "On the Pectoral and Pelvic Arches of the London specimen of *Archæopteryx*." 3. Mr. P. F. Cummings, "Studies on the Anoplura and Mallophaga, being a Report upon a collection from the Mammals and Birds in the Society's Gardens." (Part II.) 4. Lieut.-Col. J. M. Fawcett, "Notes on a Collection of Heterocera made by Mr. W. Feather in British East Africa, 1911-13."

Colonial Institute, Hotel Cecil, Strand, W.C., 4 p.m. Professor F. Watson, "Richard Hakluyt: a Pioneer of Colonisation."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Address by the President, Sir Bernard Mallet.

Wednesday, November 22...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Mr. L. Urquhart, "The Financial Position and Economic Development of Russia."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Dr. J. H. Rose, "Carlyle's 'French Revolution.'"

Thursday, November 23...Swiney Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture V.)

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. A. H. Pollen, "The Jutland Victory."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. J. S. Peck, "The Parallel Operation of Electric Power Stations."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Address by the President, Mr. F. E. Wentworth-Sheilds.

Friday, November 24...Swiney Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture VI.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—November 17, 1916.

Journal of the Royal Society of Arts.

No. 3,340. VOL. LXV.

FRIDAY, NOVEMBER 24, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 27th, at 5 p.m. (Howard Lecture.) JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." (Lecture I.)

WEDNESDAY, NOVEMBER 29th, at 4.30 p.m. (Ordinary Meeting.) DUGALD CLERK, D.Sc., F.R.S., "The Internal-Combustion Engine." The HON. SIR CHARLES A. PARSONS, K.C.B., LL.D., D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Friday, the 17th inst. Present:—

Sir William Duke, K.C.S.I., K.C.I.E. (Chairman of the Committee); Sir Arundel T. Arundel, K.C.S.I.; Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I.; Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.; William Coldstream, B.A., I.C.S., retd.; Sir Frederic W. R. Fryer, K.C.S.I.; Sir Henry Evan M. James, K.C.I.E., C.S.I.; Charles Campbell McLeod; Sir John Ontario Miller, K.C.S.I.; Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with Sir Henry Trueman Wood, Secretary of the Society, and S. Digby, C.I.E., Secretary of the Section.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 22nd, 1916; The RIGHT HON. LORD CARNOCK, G.C.B., G.C.M.G., G.C.V.O., K.C.I.E., British Ambassador in Russia, 1906–1910, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Chrimes, Charles, Holmcroft, Wilbury Villas, Hove, Sussex.

Hansard, George Albert, B.Sc., LL.M., Auckland, New Zealand.

Lindsay, Stuart Currie, P.O. Box 830 Victoria, British Columbia, Canada.

THE CHAIRMAN said he felt highly honoured at having been invited to take the chair on this occasion, and to have the opportunity of introducing his friend Mr. Leslie Urquhart, who had kindly consented to give a paper on "The Economic Development of Russia and Britain's Interest therein." There was no one more competent than Mr. Urquhart to speak on this question, because he had been one of the most energetic and zealous promoters of the use of British skill and industry in assisting in the utilisation of the vast resources of our gallant ally, the Russian Empire.

The paper read was—

THE ECONOMIC DEVELOPMENT OF RUSSIA AND BRITAIN'S INTEREST THEREIN.

By LESLIE URQUHART.

The object of this paper is, firstly, to consider the Russian internal and external financial position, and forecast what it is likely to be if the war lasts another year; secondly, to review the industrial resources of the Russian Empire to meet that position; thirdly, to consider the readiest means of developing those resources; fourthly, to show in what way this development is likely to interest and attract British capital; and, lastly, but not least important, what are the moral forces which will bring about the rapid development of those resources.

FINANCE.

From the international point of view the question of the amount of Russian foreign indebtedness is one of great importance, as it concerns the question of Russian financial stability and credit in the comity of the nations of the world; and to this country especially it is a matter of intense interest, as we are steadily becoming, and will be if the war lasts another year, Russia's largest creditor.

The Russian Minister of Finance on October 17th last, when giving an outline of the Budget for 1917 before the legislative bodies, stated that war expenses (which were not included in the Budget of revenue and expenditure) for the two years of the war to August 1916 aggregated £1,772,000,000. In order to obtain some idea of what the National Debt may be if the war lasts, say, to the end of October 1917, it can be estimated on the basis of figures given in the Budget that this will add another £1,635,000,000. Thus the total national indebtedness will have

increased by £3,407,000,000, in addition to the £882,000,000 National Debt on January 1st, 1914.

The national revenue and expenditure before the war was about £350,000,000. Notwithstanding the loss of some £60,000,000 by the abolition of the spirit monopoly, the amount estimated to be obtained according to the State Budget for 1917 is £400,500,000, thus giving evidence of the country's resources. The vodka prohibition had an immediate effect, and was the direct cause of greatly increasing the savings of the people. The average increase in Savings Banks deposits for ten years before the war was under £10,000,000 per annum. Since the prohibition the total increase in deposits for 1915 was £80,830,000, and for the first six months of 1916, £98,630,000. The total deposits at July 1st, 1916, amounted to £320,000,000, and securities deposited £110,000,000.

This increase is a small proportion of the increased savings of the nation, as savings banks before the war were only established in populated centres, and not in every large village in the country. Measures are being taken greatly to increase the number. The people's savings are at the disposal of the Government, and to a great extent can be used for the development of the country. Cessation of the vodka monopoly, therefore, has increased efficiency, and has put more money into the National Exchequer than could ever have been obtained by revenue derived from the sale of vodka.

Granted that the war is over by the autumn of next year, and that the Russian National Debt will be about £4,300,000,000, additional taxation will have to be imposed to provide for interest and sinking fund, combined, say, 5½ per cent., calling for, say, £220,000,000 per annum over a period of years. It is probable that the capitalisation of pensions to families of those killed and maimed, and compensation to those who have suffered by the war, and for the reinstatement of railways and devastated districts, will call for, say, £50,000,000 per annum, making the total increased taxation caused by the war, say, £270,000,000, of which £50,000,000 is already provided for by the increase in the 1917 Budget.

It cannot be denied that the present state of development and trade of the Empire will make this additional burden of taxation heavy for the people to carry, but the rapid development of means of communication and growth of trade and industry will make it possible for the boundless wealth of the country gradually to liquidate the debt caused by the war.

A comparison of the aggregate amount of the State debt of various Powers and the *per capita* indebtedness of each individual citizen as at January 1st, 1913, shows:—

Countries.	Total at 2*s.* per rouble. £	Per head. £	*s.*	*d.*
France	1,166,575,000	29	10	0
Germany	955,971,000	14	12	0
Russia	895,787,000	5	6	0
Austria-Hungary	696,070,000	13	10	0
United Kingdom	679,587,000	14	16	0
Italy	503,601,000	14	10	0
Spain	352,479,000	17	18	0
Portugal	176,640,000	29	12	0
Belgium	104,464,000	21	10	0
Holland	94,041,000	15	0	0

It will be seen, therefore, that the Russian National Debt is the lowest per head of population of any country in Europe.

Exchange and Trade Balance.

The fall of the exchange value of the Russian rouble during the war by about 30 per cent. has been greatly accentuated by the blocking of the Black Sea. The principal items of export from Russia are low-value crude products and foodstuffs: wheat, timber, eggs, butter, etc., which cannot stand high freights. The exports through the northern port of Archangel, which is frozen up for some months in the year, or through Vladivostok in the Far East, were small, while the imports of high-priced machinery, munitions, and equipment for army and fleet have been enormous. The result shows a large trade balance on the wrong side, which for 1914 amounted to £14,000,000; while in 1915 this had risen to £66,000,000.

Similar increases in imports over exports may be noted in other countries; but rich countries, which have capital placed abroad have interest in gold payments on this capital coming in to restore the balance, and the trade balance on the liability side becomes a financial balance on the assets side, which contributes to maintain the exchange.

Great Britain, according to a statement made by Mr. Lloyd George, has investments in the colonies and foreign countries aggregating £4,000,000,000 sterling (this figure is probably underestimated), and the yearly revenue from this capital equalled about £200,000,000.

The international exchange value of the monetary unit, which is the criterion of the intrinsic valuation of the financial position of any country, must, of course, finally depend on the balance of foreign trade in favour of that country, and of the import or export of gold, as international exchange does not recognise any

other medium of payment in adjusting the balance of foreign trade.

What is Russia's position in this respect? According to the statistics of the Russian Ministry of Finance, the foreign indebtedness of Russia before the war exceeded £500,000,000, requiring a yearly payment abroad of over £25,000,000. To this has to be added interest, etc., of municipal, private railway, and company issues, and private indebtedness, also short-term credits granted by foreign banking establishments. In view of the insignificance of Russia's merchant shipping, Russia pays abroad large sums of money for sea freight; and, finally, considerable sums are expended abroad by Russian travellers who visit health resorts.

Debt Service Payments Abroad.

It is impossible to estimate accurately such payments, as they cannot be exactly known even by the Government; it would certainly not seem an exaggeration to take this at £20,000,000, which, together with the £25,000,000 interest payable abroad on the Foreign Debt of the State, brings the total yearly payments of the nation on foreign capital indebtedness to, say, £45,000,000. Russia's total borrowings abroad since the beginning of the war had by October of 1916 grown to somewhat over £500,000,000. It is probably not an over-estimation to reckon that should the war last another year Russian foreign indebtedness to the end of October 1917 will reach, say, £900,000,000: the greater part of this will be due to Great Britain. It should be mentioned that the new as well as the old foreign debt is included in the total of the National Debt previously estimated at £4,300,000,000. If we take it, therefore, that before the war the annual payments abroad were, say, £45,000,000, and that by the end of October 1917 Russian foreign indebtedness will have increased by another £900,000,000, necessitating the payment in interest and sinking fund at, say, an average of 5½ per cent. per annum, of £50,000,000 a year, the total payments due abroad after the war will be not less than £95,000,000 per annum. These calculations are, of course, assumptions, and cannot be taken as definite; but they are based on the best information that could be obtained, and for the purposes of this paper may serve to give some idea of what the future position is likely to be.

For the covering of £45,000,000 payments abroad before the war the only item available was the excess of Russia's exports over imports, which during the period from 1908 to 1912 showed an average of some £35,000,000 per annum. It follows, therefore, that if the balance of foreign trade after the war remains at only what it was before the war the adjustment of the financial balance-sheet will require payments abroad in gold to the extent of some £60,000,000 per annum.

The production of gold in Russia is, on an average, only about £6,000,000 per annum. For the adjustment of the foreign financial balance-sheet, therefore, one of two methods only could be adopted: either to export the gold in the hands of the Government Treasury, or to contract new debts. The country cannot permit the export of gold, as this would cause the dislocation of the gold currency and the disorganisation of the whole of the economical and financial system of the country. To adjust foreign accounts by means of an increase of foreign indebtedness at the end of the war, when almost all Europe will be in need of finance, will certainly be difficult. There only remains, therefore, one remedy for Russia, and that is to increase exports generally, to increase to the maximum the value of her exported products; to export not crude, but high-priced manufactured or semi-manufactured articles; and, further, in order to keep her gold in the country, to purchase nothing from abroad which she can produce at home. This policy, which is undoubtedly the policy of the nation and the Government to-day, and is urgently called for by the necessities of the nation, will, if carried through without delay, create in a very short time a flow of gold into the country, will gradually liquidate the paper currency and reinstate the gold currency, and will restore the international or purchasing value of the rouble to its normal rate.

The Exports.

A summarised analysis of official returns of the average yearly value of exports for five years from 1909 to 1913 (the values being fairly constant for each year) shows how predominant is the agricultural character of the country, for, of a total yearly average value of exports of £142,280,000, foodstuffs and live stock account for £90,590,000, or over 63 per cent. of the total, crude and semi-manufactured goods £49,000,000, and manufactured articles only £2,690,000 a year.

Under the heading of foodstuffs, wheat alone accounted for £67,000,000, or over 48 per cent. of the total Russian exports, and constituted the chief basis of Russian national prosperity. Nevertheless, Russian agriculture yields considerably

less per acre under cultivation than any other country in Europe to-day.

Countries.	Average for 1901-1910. Wheat. lb. per acre.	Rye. lb. per acre.	Barley. lb. per acre.	Oats. lb. per acre.
Russia (50 Governments), not including Siberia	506	626	680	640
Austria	1,133	1,093	1,200	973
Hungary	840	–	1,053	946
Germany	1,826	1,466	1,693	1,626
France	1,200	933	1,120	1,066
United Kingdom	1,986	–	1,693	1,573
Belgium	2,093	1,933	2,386	2,146
Roumania	1,053	786	853	746
Serbia	746	546	680	466
Bulgaria	653	733	706	653

Even Serbia and Bulgaria compete successfully with Russia. As regards Belgium, Germany, and the United Kingdom, they represent at present an unattainable ideal. This is not attributable in any way to difference of soil—Russian private-owned land stands on a higher level of productivity by some 25 per cent. than peasant land. But it is the peasant lands that matter and the level of the peasant masses which tells.

Germany, under approximately the same natural conditions as Russia, has been able to increase its productivity year by year, while the Russian landowner is still dependent on climatic conditions, and receives from the land what God gives him, and not what he intelligently and consistently demands of it. If, under the conditions of the past ten years, Russia produced 20·3 per cent. of the total world's harvest—and, particularly in 1907 to 1912, put on the world's market 19 per cent. of the total wheat, 24·3 per cent. of oats, 48·1 per cent. of rye, and 31·6 per cent. barley—it is clear what position Russia could occupy if her agriculture were placed on a high level. If her harvest were increased to double the quantity only, this would alter the economical position of the people and the State.

Eggs.—Eggs occupy second place in value of exports under the heading of foodstuffs. In 1910 Russia exported 1,777,000,000 eggs, to the value of £3,130,000. In 1913 there were exported 3,752,000,000, to the value of £9,639,000. The export was principally to England, which takes 40 per cent. of the whole, while Germany and Austria between them used to take the greater part of the remainder. Before the war Great Britain obtained more than half her total supply of eggs from Russia, and this importation was gradually increasing. In other words, 7,000 eggs per minute were rolling out of Russia in 1913, of which the good Russian hens were laying 2,800 eggs per minute for Britain, and they are anxious to do more.

Butter.—The Russian butter trade during the last few years has been continually increasing. In 1896 the export was only 10,000 tons, of a total value of £700,000. In 1913 exports had increased to 77,000 tons, of a total value of £7,160,000. During seventeen years the export had increased seven and a half times and the value ten times. Practically the whole success of the butter trade was due to Siberia. Great Britain in 1913 took 45 per cent. of the total export, Germany 35 per cent., and Denmark 14 per cent. On the English market Russia has only one competitor, namely, Denmark, the productivity of which country has reached its highest limit, and which supplied 40 per cent. of the total butter imported into the United Kingdom, the Colonies about 25 per cent., and Russia under 20 per cent.

Russian butter has a great future before it, not only in England, but in Germany, which received 55 per cent. of its butter imports from Russia; other European countries, as also the United States, from being exporters, are gradually becoming importers.

The Beet Sugar Industry is also becoming one of great national importance. The industry is well developed on modern lines; the yield of roots per acre and the percentage of sugar from the roots are almost on the level of Germany. The production of sugar is at present at the rate of 2,000,000 tons per annum, and can be increased very greatly. It is expected that Russia will take a predominant position in the beet sugar trade, and that eventually the production will be the largest of any country in Europe. In 1913, owing to the limitations imposed by the International Sugar Convention, only 200,000 tons of sugar were exported.

After the war the Beet Sugar Convention will doubtless, so far as Germany is concerned, be cancelled, and will permit Russia to export very much larger quantities of sugar than heretofore.

Flax.—In the growing of flax Russia occupies first place in the world, and practically monopolises the world's market. Russia collects from her fields ten times as much as all the other countries together. In 1913 her exports were valued at nearly £9,000,000. The principal importers were England, Germany, and Belgium in almost equal quantities. The yield per acre, however, owing to the primitive methods

employed, was only about half what it is in other countries.

Cotton.—The cotton fields of Central Asia and the Caucasus have been continuously increasing their production for a number of years past, and are now giving nearly 300,000 tons of raw cotton per annum. With the large areas of virgin land steadily coming under irrigation the production will continue to increase rapidly, and in future the import of raw cotton will no longer be witnessed.

The exports reviewed are the principal ones, and it would be tedious to review others.

Result of Substitution of Scientific for Primitive Methods.

The figures of yields per acre I have quoted show the immense difference between the potential possibility of Russian agriculture and the actual position. Russian agriculture in all its branches is in the primitive state. It lacks organisation and modern appliances. Further, the ground does not receive back what it gives, and the equilibrium is easily upset. In the past fertilisers have practically not been used, and only lately has any progress been made in this direction. Compared with other nations, therefore, the Russian peasant has a great deal of leeway to make up. Germany, for instance, uses 135 lb. of phosphoric acid, potash, and nitrate per acre; Holland, 160 lb.; Belgium, 328 lb.; while Russia at present only uses 6 lb. per acre. On a parallel with this is the very insignificant use of animal manure.

The fundamental reason for all this is the same primitiveness. The Russian peasant produces almost exclusively wheat, for which there has long been a demand on the world's market. Having exhausted his field, he does not go over to more intensive cultivation by fertilising the soil, but, thanks to the plenitude of virgin land, moves from the exhausted position to new areas where land is free and arable. In this manner in olden times he colonised the whole of South Russia, and at a later period occupied Siberia; but the world's increasing demand and the higher prices obtaining for produce will naturally call for more intensive exploitation of the soil, as it has done in Siberia. That the peasant is quite capable of assimilating more scientific methods once shown to him to be of advantage is proven by the large yield obtained by the peasant farmer in the growing of beetroots, both per acre cultivated and percentage of sugar obtained from the roots. The past ten years have seen a gradual process of evolution in this direction, and every year sees a greater rate of progress, as the figures I have quoted tend to show. Large works are being established on the Volga and elsewhere for the production of fertilisers. Intensive agriculture would give a surplus of corn for cattle, which again would strengthen the land, and would mean at the same time intensive breeding, which would make it possible to export meat, butter, and eggs, in ever-increasing quantities after providing amply for home requirements.

The extensive development of industries in most of the Eastern European countries, and the consequent growth of town population, has gradually decreased the production in these countries of home-grown foodstuffs per head of population and increased the necessity for imports. Russia is only commencing her industrial history. Her town population equalled in 1911 only 13·7 per cent. of the whole, while in Germany and France between 50 and 60 per cent. lived in towns, and in England nearly 80 per cent.

The Census for 1915 showed that the population of the Russian Empire had reached 182,000,000, and the yearly increase is at present about 2½ millions. Over 86 per cent. of this population lives on the land. The total area of the Empire is some 8,600,000 square miles, and the land under cultivation in European Russia is capable, as I have tried to show, of very much greater productivity, while in Asia the Empire possesses almost unlimited areas ready for cultivation. This, after all, is the sound fundamental position of the Russian Empire as a great potential producer of foodstuffs; and it may be stated that, granted certain conditions, which I will deal with later, Russia may quickly become the predominant supplier of foodstuffs and raw material of the world.

Timber.

Timber, after agriculture, occupies the second place of importance in the natural resources of the Russian Empire, and second place after wheat in value of exports, having increased from a total of 6½ million pounds sterling in 1905 to 16¼ millions in 1913. Notwithstanding this rapid increase, the exploitation of the forests in Russia is still on a primitive basis; but as regards the reserves of timber the Russian Empire occupies a unique position in the world, and Russia henceforward must become the predominant supplier of timber to the European markets.

As to timber productivity, available statistical

material enables us to divide the civilised countries into two groups: in the first of these, as shown below, are included those countries the forests of which are insufficient to cover their own needs; and in the second those countries owning such an area of forests as to enable them to export timber to the world's markets.

In the First Group are Included:

	Acres.
Germany (without its Colonies) .	34,587,000
The Balkan States	25,542,000
France (without its Colonies) . .	24,426,900
Spain (without its Colonies) . .	16,059,600
Italy (without its Colonies) . .	10,130,400
Great Britain (without its Colonies)	3,037,500
Other European Countries . . .	5,783,400
	119,566,800

In the Second Group are Included:

	Acres.
The Russian Empire (including Finland)	1,456,917,400
Canada	800,442,000
United States of America . .	606,015,000
Sweden and Norway	65,269,800
Austria-Hungary	52,868,700
	2,981,512,900

The forests in the first group contain only 4 per cent. of the timber, whereas those in the second group represent 96 per cent. of the total. Russia accounts for nearly 50 per cent. of the grand total afforestation of the world; but this does not include the vast areas of unexplored forests in Siberia. Only two of the Siberian provinces—Yakoutsk and Yenissey—represent six times the size of France and Germany together. The figures quoted do not alone give quite a definite idea of the position. The part which each country occupies in the world's market must also be taken into consideration.

The forests of Norway are not very extensive, and exploitation has been carried on for a considerable period, having been commenced in the Middle Ages. Such exploitation has resulted in the country being denuded to a considerable extent. This exhaustion is strongly reflected in the rapid decrease in exports. In 1900 Norway exported 428,671 standards; in 1913, only 223,576 standards; and in 1913 Norway imported 119,032 standards of Russian timber. During fourteen years on balance, therefore, Norway has decreased its exports of timber by about 70 per cent. Norway cannot be a serious competitor to Russia.

Sweden is in a similar position, as its exports of timber are also decreasing. In the world's market of the future Sweden will not count.

The United States for many years has destroyed its forests in the most spendthrift manner. At the present time some of the States which formerly abounded in forests are denuded. Hence the United States is compelled to import timber of every kind for the requirements of its industries. The United States Government is now taking energetic steps to preserve the forests, but the shortage of timber will necessitate resort to imports from the forests of Canada, the forests of which at the present time are in many respects inaccessible; and Canada, when the time comes, will probably have her work cut out to supply her own requirements and those of the United States. With such a position in the American continent Russian forests constitute the principal source from which the various European countries will draw to cover their ever-increasing requirements of timber. Russia is guaranteed the possibility of selling as much as she can export for many generations to come.

Of the total exports of Russian timber, Great Britain has taken 40 per cent. in bulk and in value. The total imports of timber to Great Britain from various countries in 1900 was £25,084,000, and Russia's share in this was only £6,203,000; but in 1913 the United Kingdom imported timber to the value of £29,998,000, of which Russia supplied £13,622,000.

These statistics show that Russia is gradually taking the place of other countries on the British markets. After the war the position will be still further improved. The Northern ports, which were the only ones open during the war, are now better equipped, and railway connections with the main lines have been greatly strengthened. As a result, Russia will free herself from German influence.

In this connection Germany's *rôle* is striking. She established extensive industries at the mouths of the rivers Niemen and Vistula for the working of Russian crude timber, from which she received all the profit, and exported the high-priced manufactured article to all countries in Europe. By means of high Customs rates on prepared timber Germany compelled Russia to supply principally raw material.

Germany cannot dispense with Russian timber, which in 1913 contributed 50 per cent. of Germany's total timber imported. After the war Germany's requirements will be greater than ever before, particularly as the Galician forests of Austria-Hungary, which previously supplied Germany with some 30 per cent. of her timber requirements, have, to a great extent, been

destroyed. Russia's future policy will be directed to the construction of extensive enterprises in North Russia, the discontinuance of the export of timber surrogates to Germany for the production of wood pulp required in the manufacture of paper, and the conversion of this in Russia, for the demand of the world's market for wood pulp is growing at a rapid rate, Great Britain alone having imported over £9,000,000 in 1913; while Germany, thanks to occupy a dominating position in Europe in respect to sawn or prepared timber, and in time, by gradually going over to the manufacture of wood pulp and of paper, she may monopolise this branch of industry.

The Russian forests have in front of them a truly inestimable prospect for the timber industry, which in the next few years will become the hub of the political economy of the Russian Government.

Russia, was able to export wood pulp to Great Britain to a value of £3,500,000 after covering her own requirements.

British capital has not been used up to the present in the Russian timber industry; it has been directed to the Scandinavian countries, where it has established a fairly important industry, which is now obliged to fall back on Russian crude material; while Russia, the owner of the crude material, in the past has imported every year £3,000,000 to £4,000,000 worth of paper. After the war Russia can immediately

New Trade Routes.

Until quite lately Russia has done little or nothing towards the promotion of railways or utilisation of waterways for the exploitation of her great timber resources of the North. Felling rights on forest lands, which in the North practically belong entirely to the State, were only granted on short-term leases of four years, which made it impossible for the lessee to risk capital expenditure in roads, forest railways, dams, sluices, etc., as this expenditure could not be returned in this short period. For

these reasons the capital invested to-day in this very important branch of Russian industry is insignificant.

In the whole of Northern Russia there has hitherto been only one railroad that connected the railway systems of the Empire with the Polar sea (Vologda-Archangel), and this railroad leads into the port of Archangel, which is icebound in winter. Being cut off from Western Europe owing to the closing of the Dardanelles and the Baltic, Russia hurriedly commenced the construction of a railway from Petrozavodsk, near Petrograd, to the new port of Alexandrovsk, in the Mourman Gulf, which will be open for traffic in January next. The new port is open to shipping all the year round, is accessible to the largest ocean-going ships, is the nearest to the United Kingdom, lies near an open sea-way, and is nowhere shut in as her other ports are. This new railway route, with its open-sea passage, opens a new page in the history of the exploitation of the North of Russia and Siberia on the one hand and the connection between Russia and England on the other. The sea route will be shorter to the United Kingdom by about a day than from the Baltic ports. The new port will divert a huge traffic which, when the Finnish and Baltic ports were icebound, was carried in pre-war times by railway to Germany, mainly to the great collecting and distributing port of Hamburg; so that consignments of grain, agricultural produce, eggs, etc., which found their way to the United Kingdom through Hamburg, and to a small extent through Denmark, will be able to come direct, and will thus do away with the middleman's profit and the grip Germany was getting over Russian trade.

In addition to this railway, a scheme for the construction of a new line linking up the new Northern line (near the Sarotsk Bay on the White Sea) with Perm is under consideration. This railway will still further develop the North and bring the products of Siberia and the Urals much nearer to the markets of the world, especially to Great Britain.

In order to realise the importance of these new northern railways in the exploitation of the northern forests, it is only necessary to state that if the exploitation of the forests of the Archangel and Vologda Governments which will be opened up by these railways were brought into line with the average of the rest of European Russia, and the income was taken on the very lowest normal Russian rate of 3*s.* 6*d.* per acre, the Government Treasury would receive from the exploitation of the forests of these two Governments alone a net yearly revenue of £26,000,000, instead of only £516,681, which was all that the Government realised in 1913.

The Question of Imports.

In dealing with the financial position I have sought to bring out how vital it will be for the Empire to restore the exchange value of the rouble and re-establish the financial position of Russia amongst the nations of the world. The inherent resources of the country have so far scarcely been touched. The future growth of exports will be colossal—of snowball nature—especially, as pointed out, in the direction of agricultural and forestal products. But it is not alone in exports that Russia in the future can improve her position. She now imports to a considerable extent articles that she can produce herself, as reference to the statement of imports of 1913 will show:—

	£	£
Plants and seeds	2,913,500	
Fresh fruit, lemons, nuts, and plums	2,477,900	
Fish and oysters	3,820,200	
Tallow, animal fats, and beeswax	2,025,300	
Prepared leather and manufactures of leather	2,789,600	
Carpentry and fretwork	667,900	
Boot blacking	600,000	
Vegetable oils	575,600	
Resin and pitch	494,700	
Wood pulp and cellulose	219,600	
Higher class paper	1,100,000	
Toys	992,400	
Raw and manufactured silk	4,247,000	
Thread and yarn	3,006,900	
Woollen goods	4,582,100	
Lace	765,500	
Wines	2,058,800	
Furs and pelts	1,632,400	
Paraffinum and vaseline	239,500	
Live stock	1,761,500	
Bark tanning for tanning	771,900	
Flax, hemp, and articles thereof	708,400	
		37,910,700
Bar iron, steel implements, tools, nails, constructional material, drain pipes, glass physical apparatus, hardware, etc.	15,279,400	

	£	£
Chemical goods, pharmaceutical goods, spices	4,749,700	
Coal and coke	8,777,000	
Machinery	12,944,700	
Agricultural machinery	3,984,500	
Raw cotton	11,404,100	
Other goods	28,999,900	
		86,139,300
		£124,050,000

An adverse trade balance of some £60,000,000 has been calculated. Let us examine how a part of this can be met if economies are effected. Amongst the imports we find that fresh fruit accounted for £2,477,900, fish and oysters £3,820,200, tallow and beeswax £2,025,300, leather in finished form £2,789,600. It is absurd that these edibles and leather should go to Russia, which produces the finest fruit in great quantity, and the rivers and seas of which abound with fish as do those of no other country in the world.

There is also a large import of fretwork, flax and yarn, furs, live-stock, plants and seeds, etc., which aggregate some £38,000,000, all of which articles are produced in the country in large quantity and sold locally very cheaply, but owing to want of means of communication and organisation do not reach the market.

Of other items given above, it need hardly be mentioned that the import of coal and coke to the value of £9,000,000 is an anomaly, but was due to the intensive development of industries in 1913. Raw cotton for a number of years has been imported into the country at the rate of 200,000 tons a year, to the value of some £11,400,000. If the country would reduce the import of these articles by only 50 per cent. this alone would cover half the deficit which we have calculated.

It will be abundantly evident from the analysis of the figures of imports that a very great decrease in the sums paid abroad is bound to take place, and almost immediately. These decreases in imports, together with the advantageous position of the exports which have been here described, make it certain that the balance of trade can be easily adjusted after the war to cover any deficit in the financial balance, and even to leave a large surplus on the right side.

As to the future, there can be no question that the sound intrinsic position of the trade balance will make it possible for the Russian Empire to meet any possible international financial obligations which she may have incurred through the war many times over.

Railway Construction.

The Government and people of Russia realise that, whatever the financial position after the war, further loans will have to be floated to carry out a policy of intensive development, and that this increased capital expenditure for productive purposes will increase the deficits; but they realise also that by this means only will they be able to create conditions which will make it possible to exploit the boundless wealth of the country, and thus quickly liquidate the debts caused by the war. The most important means towards this end is the development of railways. It is the absence of adequate means of communication which has prevented Russia from being the richest and most prosperous country in the world to-day. In this respect it is very significant of the strong feeling of the country that, although the nation is at war, provision of £30,000,000 is made in the Budget for 1917 for expenditure on construction of new railways. At January 1st, 1915, the length of railways of general importance was about 50,000 miles, of which only 6,744 miles were in Siberia. The United States had in 1913 a railway system of over 266,000 miles; the population of the United States is, roughly, 97,420,000, and its area is 2,973,000 square miles. In other words, the United States, with a population, roughly, of only one-half, and an area of only one-third of the Russian Empire, has more than five times the mileage of railways.

Even in European Russia the peasant has to transport his agricultural produce an average distance of thirty miles to the railway over bad roads, often, in fact, mere tracks, and he can, on the average, do the journey only twice a week, under the best conditions of weather. At certain seasons the transport is impossible. It will be evident what an enormous addition to the productive power of the country it would make if the peasant had to travel an average of, say, only eight miles, as in the Transatlantic Republic, and could, therefore, do his work in one day instead of one week. Apart from this, horse-transport necessitates additional capital expenditure in equipment, and it is officially estimated that it costs the Russian peasant on an average not less than 28s. per ton to carry his produce to the railway. Without continual connection with the market it is difficult to imagine a systematic industrial system. The urgent need of an extended railway system may be seen from the intensive working of the existing system, which in 1912 carried on average 8,000,000 tons

per mile of railway. In the United States it averages only 5,000,000 tons per mile; in France and Hungary 3,200,000. Such intensive work is owing to the fact that the growth of the system has always been behind the general development of the country and its transport requirements.

The extension of the railway system is considered by the Government and public opinion to be a question which must not be delayed. It is officially estimated that at least 4,000 miles must alone be constructed every year to cover the average 8 per cent. yearly growth of traffic on the railway systems. And so strong and unanimous is the feeling that the Government has already approved and authorised a large programme entailing the immediate construction of some 30,000 miles of new railways of national importance, and the construction of many more thousands of miles is under consideration. As an indication of the strength of public opinion in this matter it may be mentioned that an issue of railway bonds to the value of £35,000,000 made in Russia in October last was subscribed for by the public four times over.

Iron and Steel.

With the above-mentioned railway construction in view, also repairs and renewals in all directions consequent on the destruction caused by war, there will come an enormous demand for iron and steel; and after the war such demand will be far beyond the present productive capacity of the country. Russia, however, has suffered so much during the war from the lack of railways that at whatever cost this shortage will be made good. For a time, therefore, and although this means the export of gold and payments abroad, rails, rolling stock, machinery, and constructional iron will be imported to meet demands. Meanwhile new railways will open those almost inexhaustible deposits of iron ore and coal at present known, but inaccessible, and which are lying unexplored. The large requirements creating high prices will naturally continue still further to stimulate industry as it has done during the war. With the return of the millions of workers at present under arms the pace will be quickened, and the time is not distant when Russia will take her place among the great producers of iron and steel of the world.

Russia's production of pig iron for 1913 was only 4,500,000 tons, that of the United States some 30½ million tons. This comparison is a very conservative criterion of the prospective requirements which the present and future iron and coal industries of Russia have to meet, and there can be little doubt that we have beginning in Russia to-day a repetition of the intense development of these industries which has been going on for the last thirty-five years in the United States. There is room here for many years to come for British enterprise and British capital, and to those Englishmen who take a hand the Russian Government and the Russian people will offer a very hearty welcome, for it is recognised that with British aid the process will be greatly quickened.

Britain's Help in World's Railway Construction.

It may be of interest here to note that Great Britain has always played a leading part in the financial development of railway systems of countries supplying her with foodstuffs and raw material. British capital was freely invested in such undertakings. From 1907 to 1913 alone the total railway issues in the United Kingdom reached the enormous figure of £396,735,950, allocated as follows:—

	£
India	19,655,125
The Colonies	118,623,776
Foreign Countries . .	258,457,049

During this period, however, British capital almost entirely ignored Russian railways, notwithstanding that Russia had yearly been growing in importance as a supplier of food. The interests of Great Britain strongly demand new and increasing outside sources of supply of food and raw material. With the increase of its population and the development of its industries the United States, which up to now has supplied about 50 per cent. of British requirements, although increasing its production yearly, has to diminish its surplus exports of wheat and agricultural products to this country.

Great Britain, in the interests of supplying her population with foodstuffs and her factories with material, has in the past invested £1,521,041,000 in issues for construction of railways outside the country. A great deal of this money has been invested for this purpose in countries like Argentina, Brazil, Chile, Cuba, Mexico, Peru, Turkey, etc. Surely, then, railway issues, the interest on which is guaranteed by the Russian Empire, with its boundless wealth and teeming population, with all its resources for rapid and successful economic development, and being geographically better placed for our markets than

any other food-producing country, present a safe and profitable investment.

Mining and Metallurgy.

The mineral wealth of the Russian Empire is recognised to-day by competent authorities as offering enormous possibilities. The Caucasus, the Urals, Central Asia, and Siberia, all contain vast areas of highly-mineralised ground of great promise asking for exploration and development. Some of the deposits of gold, silver, lead, zinc, and copper ores which have been opened up and developed are of world-wide importance and extraordinary value; iron, manganese, magnesite, and all materials necessary for smelting abound; vast salt deposits exist, with coal and sulphur in close proximity for alkali and fertiliser industries; extensive deposits of asbestos and graphite, and basins of the finest coal, petroleum, and oil shales are well known. The North Urals produce 95 per cent. of the world's platinum; there are gold placers and deposits of tin, wolfram, vanadium, and other of the rarer metals and precious stones. In short, there is hardly a mineral or metal known in the mining world to-day that the great Eastern Empire cannot produce; and yet these untold riches are lying idle and almost untouched; and, sadder still, instead of being able to supply her own industries and those of the world, there are hardly any of these metals and minerals mentioned, with the exception of petroleum, manganese, salt, and platinum, which Russia, the owner of this vast wealth, has not to import for her requirements.

Why is this? There is but one answer—want of means of communication, want of railways and means of transport. Metals and minerals are more often than not found in places remote hundreds and sometimes many hundreds of miles from the one existing trunk railway through Siberia. In a country like the United States, which is well traversed by railways, the miner has only to find, prospect, and develop large reserves of ore in his mine—the railway company will immediately lay a branch to his mine and bring him workmen, machinery, fuel, timber, provisions; the mine owner has only to extract and sell the ore raised from his mine, the Customs smelter will take care of it. The capital necessary for the mine itself is comparatively small, and this makes it possible to work small as well as large mines.

The new railways which are projected and authorised to traverse different parts of Siberia will provide the miner with the means to open up in a short time many mining districts containing large as well as small mineral deposits, and will give a great stimulus to mining and metallurgical enterprise in the country.

Siberia is a country with a good climate, well timbered, with rich virgin lands ready for cultivation, and, like all other new countries which are blessed with mineral wealth, its colonisation will be all the more rapid if the miner, the pioneer of industry, is given the possibility to open its dormant mineral riches. The settlers will follow the miners as they did in the United States, South Africa, and Australia.

The Russian Empire owes a great deal in the development of its copper, gold, lead, and zinc to British mining capital and enterprise: 50 per cent. of the copper and over 30 per cent. of the gold in Russia is produced by Anglo-Russian companies. The impulse given to the development of the petroleum industry was largely due to British capital and energy, while it was a British enterprise which introduced modern mining and metallurgical methods and processes, which permitted the working of properties that had long remained fallow, or had been abandoned in the Urals and Altai regions. The first and only large metallurgical works producing coke, zinc, and lead in Siberia are the outcome of British enterprise.

Of the more important industrial metals, the production of copper in Russia before the war was only 75 per cent. of the consumption, and of its requirements of lead and zinc 96 per cent. and 75 per cent. respectively have to be imported. The United States produced in 1913 557,400 tons of copper, and for 1916 it will probably, under present stimulus, output some 800,000 tons, whereas the Russian production of copper for 1913 was only 33,250 tons. After the war, with an intensive programme of railway construction, the expansion of the iron and steel trade, and the many manufacturing and chemical industries which have been started during the war, the requirements in these metals will increase more and more. Something has already been done in showing the possibilities and exploiting a few of the mineral deposits in the Russian Empire, but the field is so great that what has been done so far is an infinitesimal part of the possible whole.

Take the case of a single metal. In the matter of copper production Russia is to-day in about the position of the United States in 1881. The United States produced only 32,000 tons in that year, or just about what Russia did in 1913. The parallelism extends further: the Russian Empire to-day has, just as that country then

had, great copper districts lying undeveloped—how great I cannot pretend to guess. But it does not follow that it will take thirty-five years for Russia to come into her own in the matter of this metal. The way has been found, the methods of mining and treatment have been elaborated, and have become the commonplaces of the modern mining engineer, so that, in the future, years can be expected to show the advance of decades in the past. I venture to say that in 1881 a copper ore containing 4 per cent. or 5 per cent. was scarcely profitable. To-day perhaps half the production of the States comes from ores of less than half that value. Further, long-sighted business men in the United States are tô-day looking forward to the time when even their enormous deposits will show exhaustion, and are casting about for new sources of supply; it is known that their eyes are turning to Russia as the only unexploited civilised country where new sources can be found.

What is true of copper is also true of lead, zinc, and other metals.

A personal experience of twenty years' mining and metallurgical work in the Caucasus, the Urals, and Siberia, in the management and control of Anglo-Russian undertakings employing some 40,000 men, enables me to say that in this department of industrial activity British enterprise and capital are welcomed and fostered by the Government. The nation recognises that British technical knowledge, practical experience, and the capital invested in this direction is an educating and civilising influence, opens up new country and new industries, gives work and bread to the people, keeps money in the country, and for these reasons the Russian Government has never grudged the earning of large profits, recognising that without this result the capital necessary for the development of the country will not come in.

Russia's Past Share in British Investments Abroad.

Great Britain, who, similarly to France, had before the war ceded to Germany front rank in the industrial world, was undergoing an evolution in the direction of financial capitalisation. Owing to their great accumulation of wealth these two countries had become the world's bankers, and it was as necessary for them to place capital in poorer countries as it is for Russia to-day to borrow capital.

If we examine the direction of British capital to the principal countries of destination it will be found that during the period of seven years from 1907 to 1913, according to the *Statist* of February 14th, 1914, the total invested was £1,127,000,000, divided up as follows:—

	£
India and Colonies	481,529,927
Argentine	118,339,585
Brazil	88,227,036
Chili	27,563,340
Cuba	14,563,385
Mexico	33,822,322
Peru	6,988,691
United States	164,201,850
Rest of America	11,128,188
Austria	6,247,896
Bulgaria	3,819,499
Denmark	6,844,600
Egypt	6,427,577
Finland	3,441,450
Greece	3,301,644
Hungary	2,077,240
Norway	4,833,250
Roumania	4,429,875
Russia	46,214,906
Siberia	994,993
Sweden	4,556,000
Turkey	4,745,869
Other European Countries	9,280,176
China	27,805,737
Dutch Colonies	12,236,971
Japan	22,447,240
Persia	2,706,250
Philippines	2,238,283
Siam	1,102,500
Rest of Asia	175,000
Africa	2,702,603
Others	2,436,146
Total	£1,127,431,129

Chili and Cuba combined received almost as much as Russia, and Brazil almost twice as much. From now onwards the distribution of capital will doubtless be greatly modified.

The investment of capital in Russia is of advantage not only in the interests of capital alone, but it is also vital in the politico-economic interests of Great Britain that Russia should be strong. By helping the economic development of Russia, Great Britain is at the same time working in her own vital interests; the raising of Russian industry supported by a population of 200 millions represents such an enormous power that it signalises the political and economical weakening of Germany. Any weakening of Russia is at the same time a strengthening of Germany. If Russia were militarily crushed and economically bound, the master of Europe would be

Germany; and the fate of France, and later possibly even of Great Britain, would be sealed. After the war. Germany will make strenuous efforts to regain her commercial supremacy and political influence in Russia, and the war will have been fought in vain if this country does not put out every effort to develop close commercial relations, and thus establish the soundest basis for the economic and political alliance which is mutually necessary between the two countries.

That Russia can at no distant date fully liquidate her debts has already been shown; the capital sums are guaranteed by the immeasurable, if undeveloped, wealth of the country; this wealth only waits for machinery to become tangible. Great Britain is interested in this from all points of view, as the political and economical interests of both Empires are closely allied. By strengthening the Eastern Empire Great Britain is forging arms for her own defence.

Before the war the spread of civilisation in Russia was steadily making her ready for economic expansion. The intellectual development of the masses was going on rapidly. The State expenditure in 1897 on education was only £4,061,611; but this expenditure was yearly increasing, until the State Budget for 1917 provides the Ministry of Education with £21,421,202.

If the war had not broken out the country would have solved the problems as they arose. The war has forced events, as wars have done more than once in the life of Russia. Serfdom was abolished after the last Crimean campaign, and the State Duma came into being after the Russo-Japanese war.

A world's tragedy cannot be passed through without its leaving a deep impression on the psychology of the nations taking part in it, and the Russian Empire during its long history has never conducted a war in which the people have entered with such discernment. This discernment does not apply so much to the international relations as to the internal events in the country itself. The army is no longer made up of specialists, but of the manhood of the whole nation under arms. The trenches of Poland and Galicia, the mountains of the Caucasus, the training grounds at home, the workshops of the country, have seen a process of education going on for the past two years that no amount of schooling could ever give. Citizens of a mighty Empire thousands of miles apart, knowing heretofore little of each other or of the districts they lived in were brought together. Simple peasants from the plains of Russia and Siberia, hillmen from the Caucasus, Altai, and Turkestan, shoulder to shoulder with men from the towns, men of education and refinement, all living and suffering together, understanding and educating each other for those years—a real brotherhood of man, their patriotism making them conscious of their destiny and their duty to their native land. Can it be wondered at that the army and the nation have become impregnated with the conviction that the vital interests of their country, for love of which they have been fighting and giving their lives, demand, among others, certain reforms, which may be stated in a brief formula? The formula is to create by every possible means, and in the shortest possible time, favourable conditions for the rapid development of all branches of agricultural and industrial activity, for the good of the people and the strength of the Empire.

DISCUSSION.

The Chairman (the Right Hon. Lord Carnock, G.C.B., G.C.M.G., G.C.V.O., K.C.I.E.) said he was sure that those present would authorise him to convey to Mr. Urquhart their best thanks for his most interesting and instructive paper. In a small compass he had dealt clearly with some most important questions, and he had laid before them a statement which merited the most careful study, one which he hoped would stimulate British capitalists and business men in extending and developing their operations in Russia. He most sincerely trusted, and he was sure it was the hope of all, that the commercial and industrial relations between the two countries would develop and prosper, and not only would such intercourse be of incalculable material benefit to both peoples, but it would assist in strengthening those ties which had already been established on the battlefields of Europe by sacrifices made in the furtherance of a common cause. Any measures which would promote sympathy between the two countries and enlarge their knowledge of each other should be warmly encouraged, and he could conceive no better means of achieving that result than a closer commercial and industrial relationship. This war had greatly embarrassed the export trade of Russia, which was so important a factor, and it was certainly highly to be desired that the railway to the new port of Alexandrovsk should be opened to traffic as soon as possible. The observations of Mr. Urquhart with regard to the great financial position, to the great prospects in Siberia, and to the agricultural, forest and mineral wealth, deserved the most careful attention. It stirred the imagination to listen to a description of the vast and varied resources which only await capital and better means of communication to be

developed to an extent hitherto undreamed of. He hoped that in assisting the furtherance of the development British capital would not be lacking. It was now that preparatory steps should be taken to that end. If we waited until the indeterminate date of the termination of the war others would probably step in and forestall us. We should take our steps at once. The closing paragraph of Mr. Urquhart's paper enunciated in eloquent terms great truths, and he hoped they would be laid to heart. He endorsed every word that had been said. The distrust, apprehension and suspicion between Great Britain and Russia had been laid to rest for ever, and it was for all well-wishers and friends of Russia to do all that lay in their power to cement the bonds between the two countries.

Lord Weardale expressed his warm acknowledgment for an admirable *exposé* of the potentialities of the Russian Empire. All who had been acquainted for a long period, as he had, with many parts of Russia were conscious of the great possibilities which lay dormant, unfortunately, in the circumstances under which Russia then existed. In addition to those potentialities it was all-important that the soul and the spirit of the Russian people should be aroused. That was what those who admired and respected them perceived, and most of them recognised that this awful war, which none could think of without horror, would bring to some lands, and possibly to no country so much as to Russia, the prospect of an awakening to the possibilities of a great future, and, he hoped, the emancipation of the intellect of the manhood and the womanhood of Russia in a sense which up till now they had not perhaps had the opportunity of foreseeing.

Dr. John Pollen, C.I.E., added a few words of appreciation to those already spoken. It was very gratifying to hear a true description of the real state of Russia, and to hear of the great possibilities which had been so long concealed. More than a quarter of a century ago he visited Russia, and discovered nearly all the facts that had been so ably put forward in the paper. Why had these facts been concealed from the British people? In old times there were prophets in the land. The prophets of the present day were represented by the press of England; but, alas! the press of England allowed itself to be hoodwinked by the enemy and misrepresented Russia on all occasions and in all places. It was only now that the press had opened its eyes to the true facts. He was afraid that the prophets of the day were so intent on their own profits that they neglected the true prophets. The press held out the bugbear that Russia wanted India. Having heard of the magnificent resources Russia herself possessed, was it likely that she would care to hamper herself with the difficulties the English people experienced in administering India? No. He hoped the facts given in the paper would be published throughout the length and breadth of the land.

Sir Donald Mackenzie Wallace, K.C.I.E., K.C.V.O., said the paper gave a mass of valuable statistical information brought up to date. This was a thing that must be drummed into the British public. We were a thick-headed race—very thick-headed—and when we took a preconceived notion on anything it was excessively difficult to get it out of our heads. Of all countries in Europe, certainly the greatest number of preconceived notions which had assembled in the British mind was about Russia. He well remembered fifty years ago, when the anti-Russian fever was at its height, and he was regarded as a horrible Russophil; but he was happy to say that since then we had made enormous progress. This progress was not in mere sentiment, but in solid knowledge, which should produce a very great effect in the future, whether on account only of our love for a faithful ally, or even from lower motives, from that desire for national self-enrichment, which some people described as the mainspring of our policy. It was quite certain that we could not only bind to ourselves that ally who was doing such splendid work in the East of Europe, but we could at the same time have a moderate remuneration for our effort.

Sir John Jardine, K.C.I.E., M.P., remarked how extremely well the excellent statement of the case put by Mr. Urquhart coincided with the movement going on in the City of London and in the City of Glasgow to increase the possibilities of trade with Russia, now and when the war ended. He need not allude to the fact that a Russo-British Chamber of Commerce had recently been started here, and that a Russian society had been started in Glasgow. As regards the chief matters upon which capital could be expended, Mr. Urquhart had pointed out the enormous value of the agricultural products of the country, and one might say from that that money should be sent from here to develop those great fields. On the other hand, the want of fertilisers had been pointed out, so that the return would not be so rapid, and he should think, from Indian experience, that Great Britain would not gain much by undertaking the direct loaning of money to the cultivators of the soil. They might do something in the way of mining the fertilisers wherever they might be. The author seemed to be fixed on the right thing, and one that would appeal to most capitalists in Scotland and England, in developing railways. It was felt long ago in our own thickly populated country that we should not have nearly enough to live on unless we went further afield, and British capital went out to Canada and the United States in great quantity. Then it was found that the best use to put it to, in order to reach the fields where wheat might be

grown, was to build railways, and that had been carried out ever since. A similar course of action would coincide with the development of the great wealth of Russia. Mr. Urquhart himself had played a great part in the development of Russia in dealing with copper and the precious metals, and he believed they had discovered nickel lately, and shale oil in the Urals and Siberia. Wherever there were railways, and in some places where there were not, Mr. Urquhart seemed to have been; from the Caucasus to the new port in the Arctic regions which was now being built and would be working before long. It was now quite clear that the more railways there were the nearer we got to the fertile lands, and the nearer we got to the mines. In this matter we should go on the experience of Canada, the Argentine, and India, where there was a great system of railways, carefully considered with forethought years ahead as to how much development should be done. That problem was being considered by the Russian Government now, and he could see no reasons, given a firm government to begin with, and a progressive government next, why a much larger quantity of British capital should not go to Russia to found new railways. The paper had shown the possibilities of mining to be boundless, the very kind of thing in which British enterprise had long been successful. It was known that the enormous number of railways in Germany had not only increased the demand for iron and steel enormously in proportion to the mileage, as in the United States, but it had also given Germany a commanding influence in the markets of Europe. Germany had lately been increasing her trade in the markets of Europe by using that land transport, although at the same time we had outdistanced her in using our sea-going power to take our goods to the other markets of the world. If Russia were nearer to the other countries, and especially with railways, it must increase her trade enormously. With more railways would come more hotels, and with hotels would disappear many of the inconveniences experienced now when travelling in Russia. The paper was one well worthy of the Royal Society of Arts. As the development of art went with the development of commerce in our own very practical country, he hoped the paper would soon be in the hands of those captains of industry, those merchant princes who were to be found in the City of London, in Glasgow, and in the other great trading centres.

The vote of thanks was then put to the meeting and carried unanimously.

Mr. Urquhart replying, said he was deeply sensible of the shortcomings of his attempt to deal with a subject of such magnitude within the short time at his disposal. Necessarily, he had been compelled to deal with it more or less on broad general lines; but he hoped, through the medium of the Society, the paper would be of use to those who might be induced perhaps to study the subject still further, to the mutual advantage of the two countries.

The meeting then terminated.

OBITUARY.

Peter Brusey Cow.—Mr. Peter B. Cow, whose death took place after a long illness on August 27th, was a member of the Society of forty-seven years' standing, having been elected in 1869. He was born in 1847, and after being educated privately he entered the rubber works of Messrs. Cow & Co., in Factory Square, Streatham. He took an intense interest in the welfare of his employees, all of whom he knew personally, and until recent years it was a rare thing for any of his workers to leave for other employment.

Mr. Cow was a generous supporter of the Church, to which he was devoted, and his benefactions, public and private, were very numerous.

David Howard, D.L., F.I.C., F.C.S.—Mr. David Howard died suddenly on the 14th inst. as he was travelling from his residence at Buckhurst Hill to his offices at Ilford. He was the son of Robert Howard, and grandson of Luke Howard, F.R.S., who founded the well-known firm of manufacturing chemists, now styled Messrs. Howards & Sons, Ltd.

David Howard entered his father's firm (then Howard & Kent) in 1857, and soon afterwards became a pupil of Hofmann at the Royal College of Chemistry in Oxford Street. Throughout his life he took the deepest interest in the development of chemical education and research. He served on the Council of the Chemical Society, and was a Vice-President on several occasions. He was one of the founders of the Institute of Chemistry, a member of the first Council, and President for the period 1903-6. He was an original member of the Society of Chemical Industry, of which he was President in 1886-7, and he was for some years Chairman of the Chemical Section of the London Chamber of Commerce.

Mr. Howard became a member of the Royal Society of Arts in 1879. He presided at a meeting in 1884 when a paper on "The Manufacture of Gas from Limed Coal" was read by Mr. J. Alfred Wanklyn, and he took part in discussions on several occasions.

NOTES ON BOOKS.

The Tale of the Armament of Igor, A.D. 1185. Edited and translated by Leonard A. Magnus, LL.B. Oxford University Press. 1915.

The Russian language and Russian literature are receiving a great deal more attention than they did three years ago. English people are

learning the former, and thereby qualifying themselves for the study of the latter. Hitherto the few Russian authors who were known in this country were known only in translations, sometimes in double translations, an English version adapted from a French one. It is true that the difficulties, or presumed difficulties, of their vernacular compelled Russians to study other languages, and the result has been that they share with the Dutch the reputation of being the best linguists in the world.

The mediæval epic which Mr. Magnus is the first to introduce to English readers has a curious history. In 1795 Count Musin-Puskin, a well-known archæologist, bought from a monastery a volume of manuscripts, amongst which was the original of the "Slovo." It was printed and published in 1800, but the manuscript and most of the prints perished in 1812 in the fire of Moscow. The printed book thus became the original, and was so regarded till 1864, when a second copy of the original manuscript was found among the archives of Catherine II. with notes and a translation into modern Russian which was apparently made by Musin-Puskin for the Empress.

The poem seems at first to have been regarded in some quarters much as the contemporarily published "Ossian" was regarded in London, but such doubts were soon settled and its authenticity is accepted as beyond dispute.

Its author is unknown, but its date is fixed by certain references as 1185 or 1186. Its subject is an expedition (by Prince Igor, one of Rurik's descendants in the fifth generation and a kinsman of the contemporary Grand Princes of Kiev) in one of the innumerable wars which were carried on in Russia's essentially feudal period. As it appears to be the only complete poem of its own time and character amongst numerous fragments, it may doubtless be regarded as being, in Mr. Magnus's words, "one of the treasures of Russian mediæval literature."

It would be difficult to speak too highly of the completeness with which the work of editing the poem has been carried out, or of the scholarly fashion in which it has been executed. Besides the text and its translation with copious notes, there is a long introduction giving an account of the primitive geography of Russia and a summary of its history up to the Mongol Conquest (in the thirteenth century), with separate essays on the construction, composition, language and other characteristics of the poem.

Beautiful Buildings in France and Belgium. London: T. Fisher Unwin, Ltd. 12*s.* 6*d.* net.

This is a book to delight the hearts of all lovers of Gothic architecture. It consists of reproductions in colour and monochrome from rare old prints and drawings, by and after Prout, Boys, Coney, W. Callow, David Roberts, C. Wild and others, and each illustration is accompanied by a brief but adequate note by Mr. C. Harrison Townsend, F.R.I.B.A. Many of the pictures have unfortunately now acquired an added interest because the subjects which they represent exist no longer. The beautiful Cloth Hall of Ypres, of which there is a charming sketch by J. Coney, is now levelled with the ground, and only one corner of its fine tower remains standing. This was the finest of the Trade Halls of Belgium as well as the earliest to be erected, and "the restoration of the whole building had been barely completed when the destroyers robbed the world for ever of one of its fine and gracious works of art."

Perhaps the finest illustration in the book is G. Simonau's picture of the west front of Rheims Cathedral, which is almost photographic in its extraordinary care and detail. It seems scarcely conceivable that even the most barbarous of enemies should have vented his fury on a building at once so beautiful, so majestic, so delicate, and so wholly void of offence. The Cathedral has been subjected to the cruellest bombardment, till it is now but a shell-torn ruin. It is well that we have Simonau's drawing to remind us of the glory that was Rheims.

For the whole get-up of the book one can have nothing but praise. The type is admirably clear and the setting out of the pages, with their red headings and initials, is most satisfactory. Nor can any fault be found with the reproduction of the drawings, especially those in colour. For instance, in the frontispiece, which reproduces a painting by T. S. Boys of the Hôtel de Ville at Arras, the tints are most delicate and charming and another attractive page is filled by C. Wild's drawing of the south entrance of Rouen Cathedral.

GENERAL NOTES.

Distress in Belgium.—An urgent appeal is issued by the National Committee for Relief in Belgium on behalf of the Belgian children. A careful investigation has been conducted by Dr. William Palmer Lucas, Head of the Department of Children's Diseases in the Medical College, University of California; he has spent some months in the territory occupied by the Germans, and he finds that in 65 per cent. of the population the effects of two years' captivity on short rations has now become painfully apparent. The vitality and resistance to disease have been lowered, and this is due mainly to under-feeding. The result is that tuberculosis has increased by 100 per cent. Every sanatorium in Belgium is now crowded, the waiting lists of all the sanatoria have increased, and the waiting cases are now more acute than formerly. As it is impossible to isolate these acute cases, they are rapidly

spreading the disease. The only means of fighting this peril is to secure for the children a better supply of food. Contributions should be sent to A. Shirley Benn, Esq., M.P., Hon. Treasurer, National Committee for Relief in Belgium, Trafalgar Buildings, Trafalgar Square, London, W.C.

MR. PENNELL'S DRAWINGS OF MUNITION WORKS. —Mr. Joseph Pennell has been engaged for several months in making a series of remarkably fine drawings of munition works in various parts of the country. These will be shown, by consent of the Ministry of Munitions and on the invitation of the Corporation of the City of London, at the Guildhall Art Gallery. The exhibition will be opened on December 1st by the Lord Mayor, and the Right Hon. E. S. Montagu, Minister of Munitions, will speak on the occasion.

PAPER MATERIALS.—The growing scarcity of materials for the manufacture of paper has led the Bureau of Science of the Philippine Islands to make public some important data concerning the supply of such materials in the islands. For several years the bureau has been investigating the suitability of bamboo, cogon grass, abaca, and various palm fibres for paper pulp. The facts collected are regarded as evidence that an industry of great economic value could be developed. Careful surveys of some of the bamboo fields have been made. Data regarding the cost of the raw material, the quantity of bamboo available, and the cost of manufacture of the pulp show that the bamboo soda-pulp industry can be developed for a possible export trade in direct competition with chemical wood pulp at present quotations. Other countries already have utilised the information obtained from this work, which ultimately may be the means of starting the paper industry in the Philippines.

CHINESE TELEGRAPHS. — The *London and China Telegraph* draws attention to the great improvement that has recently been made in the service of the Chinese Telegraph Administration. New territory has been reached and new offices opened in fields already covered. To ensure speed in the transmission of telegrams the Wheatstone automatic system has been adopted on all trunk lines. In order further to accelerate the transmission of telegrams, three years ago the Administration began the installation of the automatic duplex system on its more important lines, the first installation being made on the Pekin-Tientsin line. In May and June this system was put into use between Pekin and Hankow and Hankow and Shanghai. The average working speed attained on the 85-mile Pekin-Tientsin line is 110 words a minute, while seventy words a minute is the average speed attained on the 750-mile Pekin-Hankow line and the 720-mile Hankow-Shanghai line. Taking into consideration the interruptions caused by climatic conditions and the great length of some lines, the speed of transmission compares favourably with that of European and American lines under similar conditions. It is the intention of the Administration gradually to extend the duplex system, and no doubt in the near future it will have been established on all important trunk lines in China, thereby doubling the capacity and reducing the delays to which the traffic would otherwise be subject.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

NOVEMBER 29.—DUGALD CLERK, D.Sc., F.R.S., "The Internal-Combustion Engine." The HON. SIR CHARLES A. PARSONS, K.C.B., LL.D., D.Sc., F.R.S., will preside.

DECEMBER 6. — C. M. WHITTAKER, B.Sc., "The Coal-Tar Colour Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

DECEMBER 13. — H. WILSON FOX, "The Development of Imperial Resources."

DECEMBER 20 (at 4 p.m.).—A. C. BENSON, C.V.O., Master of Magdalene College, Cambridge, "Classical and Scientific Education."

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m. :—

DECEMBER 14. — JOHN AITON TODD, B.L., Professor of Economics, University College, Nottingham, "The World's Cotton Supply and India's Share in it." The RIGHT HON. LORD EMMOTT, P.C., G.C.M.G., will preside.

Dates to be hereafter announced :—

LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

JAMES HARRIS VICKERY, LL.B., "German Business Methods."

CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

OCTAVIUS C. BEALE, "British Arts and Crafts after the War."

Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel."

Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

Sir C. Arthur Pearson, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

Joseph Pennell, "The Artistic Aspects of War Work."

Gabriel Gordon Cleather, "The Drum."

Francis A. Hocking, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

Robert Fortescue Fox, M.D., "British and Foreign Spas."

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

January 18, February 15, March 15, April 19, May 17.

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

January 30, February 27, March 27, May 1.

Howard Lectures.

Monday afternoons, at 5 p.m.:—

John S. S. Brame, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." Three Lectures.

Lecture I.—November 27.—The economic importance of coal—Enhanced importance in war time—Coal: the munition of war—The movement for economy—The output of coal and consumption for various purposes—Duration of supplies and economical considerations in relation to other countries—Other alternative sources of energy.

Lecture II.—December 4.—Recent developments in knowledge of composition of coal—Coal as a heating agent—As source of power—For domestic heating, etc.—The by-products from coal distillation, their relation to industry, and particularly as raw materials for munitions of war.

Lecture III.—December 11.—Directions in which economy may be realised—Economy in production—The utilisation of small and low-grade coal—Improvements by suitable preparation for market—Economy in use—By-product recovery—Economies possible from centralised systems of power generation: from extended use of carbonised coal, including gas—Low temperature carbonising schemes.

William Ripper, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

Cantor Lectures.

Monday afternoons, at 4.30 p.m.:—

Professor A. Beresford Pite, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

Juvenile Lectures.

Wednesday afternoons, at 3 p.m.:—

Alan A. Campbell Swinton, F.R.S., "Electricity and its Applications." Two Lectures.

January 3, 10.

MEETINGS FOR THE ENSUING WEEK.

Monday, November 27...Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. (Howard Lecture.) Professor J. S. S. Brame, "Coal and its Economic Utilisation." (Lecture I.)

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Inaugural Address by the President, Mr. S. G. Warner.

Tuesday, November 28...Swiney Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture VII.)

Photographic Society, 35, Russell-square, W.C., 7 p.m. Rev. E. C. Pitt-Johnson, "A Holiday in the Alps."

Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Professor G. E. Smith, "The common objections to the reality of the Migrations of Early Culture, with special reference to the Dogma of the similarity of the working of the Human Mind."

Wednesday, November 29...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Dr. Dugald Clerk, "The Internal-Combustion Engine."

Thursday, November 30...Swiney Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture VIII.)

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. J. Small, (*a*) "On the Floral Anatomy of some Compositae"; (*b*) "Demonstration on the Force for dispersal of Fruits." 2. Mr. T. A. Dymes, "A note on the Seed of *Iris Pseudacorus*, Linn."

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. F. Martin Duncan, "Some Huns of the Insect World."

Friday, December 1...Swiney Lectures, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture IX.)

Saturday, December 2...Geologists' Association, University College, W.C., 3 p.m. Mr. H. Bury, "The Palaeoliths of Farnham."

Journal of the Royal Society of Arts.

No. 3,341. VOL. LXV.

FRIDAY, DECEMBER 1, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 4th, at 5 p.m. (Howard Lecture.) JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." (Lecture II.)

WEDNESDAY, DECEMBER 6th, at 4.30 p.m. (Ordinary Meeting.) C. M. WHITTAKER, B.Sc., "The Coal-Tar Colour Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

HOWARD LECTURE.

On Monday afternoon, November 27th, Mr. JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, delivered the first lecture of his course on "Coal and its Economic Utilisation."

The lectures will be published in the *Journal* during the Christmas recess.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, November 29th, 1916; The HON. SIR CHARLES A. PARSONS, K.C.B., LL.D., D.Sc., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society :—

Collett, Leopold George, Merle House, Evesham.

Deas, Edmund Percy, 52, Larkspur-terrace, Newcastle-upon-Tyne.

Notley, Miss Mabel Emily, Larksfield, Englefield Green, Surrey.

Pegler, Alfred, 81, Palace-road, Streatham Hill, London, S.W.

Souza, Francis Xavier Da Silva e, 17, Nakayamate dori, Nichome, Kobe, Japan.

The following candidates were balloted for and duly elected Fellows of the Society :—

Barstow, Hon. George Eames, Barstow, Texas, U.S.A.

Brooker, Hon. Charles Frederick, A.M., The American Brass Company, Ansonia, Connecticut, U.S.A.

Cameron, Alexander, Government Dockyard, Massaruni, British Guiana.

Carver, George W., The Tuskegee Normal and Industrial Institute, Tuskegee, Alabama, U.S.A.

Clerk, Mrs. Dugald, Lukyns, Ewhurst, Surrey.

Cossar, Wilayat Hussain, The Watan, Lahore, India; and The University, Glasgow.

Currimbhoy, Hon. Sir Fazulbhoy, 13, Esplanade-road, Bombay, India.

Daubeney, Rev. A. R. Vaughan, East Walton Vicarage, King's Lynn.

Dhar, His Highness the Raja of, K.C.S.I., Dhar, India.

Eddy, Charles B., 62, Cedar-street, New York City, U.S.A.

Fenimore, Miss Beulah A., 147, Manheim-street, Philadelphia, Pennsylvania, U.S.A.

Garrett, Miss Mary S., Belmont and Monument Avenues, Philadelphia, Pennsylvania, U.S.A.

Glynes, Webster, Hamston House, Kensington-court-place, W.

Goodwin, William V'Alters Summers Gradwell, J.P., F.G.S., Red Heath, Silverdale, Staffordshire.

Greenwood, Thomas, 10, John-street, Hill-street, Mayfair, W.

Haidar, Haji Saiyid Jalaluddin, M.A., Aitchison Chiefs' College, Lahore, India.

Higgin, William Henry, B.Sc., The Elms, Parkstone, Dorset.

Holeman, Frederick Alfred, M.I.E.S., Jibutil Gold Mines, Morriston P.O., South India.

Horsfeld, H. E., Cuttack, Orissa, India.

Humphreys, J. Charlton, Junior Athenæum Club, 116, Piccadilly, S.W.

Hutton, J. Arthur, 15, Cross-street, Manchester.

Kershaw, Louis James, C.I.E., India Office, Whitehall, S.W.

Khan, Syed Ahmad Ali, Salimpur, Lucknow, India.

The Chairman said he had been called on to perform the pleasant duty of presiding at the meeting that afternoon, when the paper was read by the Chairman of Council, his old friend, Dr. Dugald Clerk. The subject of his paper was one which had occupied a great deal of his personal attention for many years, and with which his name was closely, and would ever be, associated. It was almost thirty-six years ago that he first had the pleasure of meeting Dr. Dugald Clerk under kindred and stimulating circumstances. He found him in his workshop at Glasgow, hard at work with his coat off and his hands were greasy and black, as an inventor's should be. He was working assiduously at his new gas engine, and he had explained to him (Sir Charles) its construction, its ingenious platinum ignition apparatus, and its two-cycle system of operation—a system now universally called the Clerk cycle—on which system many thousands of engines were now at work all over the world on land and at sea. The internal-combustion engine today ranked among the most important prime movers, and it was also the most economical in the conversion of the energy in oil or gas into mechanical work. Upon it depended all aircraft and nearly all submarines, and motor transport of all descriptions. Indeed for small and moderate powers its use was almost universal. It had become an ever-present part of our modern life, and was exercising on the community at large an educational influence in mechanics and engineering far greater than we were accustomed to suppose. It was a very important subject and one of which Dr. Clerk was a master. He took the opportunity of saying that in the near future Dr. Clerk would be assuming a very important Government position in connection with certain developments in this country. More than that he would not say then.

The paper read was—

THE INTERNAL-COMBUSTION ENGINE.*

By Dugald Clerk, D.Sc., F.R.S., M.Inst.C.E.

Motive power is of fundamental importance to industrial civilisation: without steam, internal combustion, and hydraulic power it would be impossible to support at all the forty-six

* First delivered in the Town Hall, Newcastle-on-Tyne, on September 4th, 1916, at the Meeting of the British Association.

millions of people now living in fair comfort on our small islands of Great Britain and Ireland. The labour of the scientific man, the engineer and the business man, in the long run, renders possible the very existence of this large and dense population.

The important part taken by us in the origin and development of steam motive-power is well known, and it is generally recognised that Britain stands supreme in all that relates to steam engines from the time of the condensing engine of James Watt to the steam turbines of the Hon. Sir Charles Parsons. All the intermediate stages—expansion, high pressures, compounding, tripling, and super-heating—originated in these islands. The application to pumping, mill-driving, marine navigation, and locomotive engineering began and developed here. Although the credit of steam invention is conceded to us, many of our general public and some of our engineers seem unaware of the leading part taken by England in that great field of invention covered by internal-combustion engines; they imagine that in this subject we are wholly indebted to Germany, and that the work of invention here is small compared to that of the Continent. This impression has arisen because of the indefatigable propaganda of scientific engineering Germany and the distinct bias to German methods shown by some of our prominent men. We are freely given to self-criticism, and no doubt in time of peace this characteristic is quite beneficial and useful in maintaining the desire to improve; but in times of war and change it is as harmful to underrate our own strength and achievements as it is to underrate the power of our enemies.

In the development of internal-combustion engines we have borne our full share of pioneer work. It is true that effort both in the past and present is more uniformly distributed among the nations in this field than in steam, but we hold our own in the competition towards more perfect thermodynamic methods and machines.

A very short review of the past will convince you that much has been done by England to develop engines fit for the great modern uses of stationary power production, land and water locomotion, and last, light and powerful engines for flight. The subject is one to which I have devoted much attention for the past forty years, during which these engines have developed from mere toys of one-half to three horse-power to engines of the thousands of horse-power of to-day. During that time there have been produced heavy engines for stationary purposes, light engines for motor-cars and flight, and intermediate engines for ship propulsion—all with the characteristic burning of the combustible gaseous or vapour fuel within the cylinder instead of within the boiler furnace.

My interest in the gas engine—as it was then called—began at the end of the year 1876. At that date the only types of engine in operation were the non-compression engine of Lenoir and the non-compression free piston engine of Otto and Langen. In 1876 the Lenoir engine had practically disappeared from commerce; a number were at work, but the only commercial engine was the Otto and Langen. This was a cumbersome engine, which operated with great noise and much recoil, and the largest of the type in existence did not develop more than three brake-horse-power. In that year the user of motive power had but little choice. He was practically confined to the steam engine, both for small and large powers. The motive power user of to-day is in a more fortunate position. Constructors of many types of motors compete for his favour.

These forty years have seen a marvellous development of the gas engine, and an extension of the use of different fuels has caused the old title "gas engine" to disappear in favour of the more general term "internal-combustion motor," lately shortened to "combustion motor," which includes all engines known as gas, petrol, and oil motors.

The gas engine originated, as its title shows, in a form of machine adapted to burn the coal gas of our towns; for many years past other inflammable gases have been consumed, such as producer gas in its various forms, generated from anthracite, coke, bituminous coal, and waste combustible solids like wood chips, sawdust, spent tan, and coconut shells, also coke oven gas and blast furnace gas; light volatile hydrocarbons are used, such as petrol and benzole; heavy hydrocarbons and sometimes coal tar. Even alcohol is applied to the purpose of actuating such engines.

In 1876 the total power generated by gas engines in the United Kingdom did not exceed 2,000 b.h.p., while in 1907 the final report of the first census of production of the United Kingdom shows that factories alone had at work a total of 680,177 h.p., while agriculture employed 98,785 h.p. of gas, petrol and oil engines.

In addition to this there were in use in motor-cars and motor-cycles not less than 750,000 h.p.

generated by petrol engines. The total power generated by internal combustion was thus:—

	Horse-power.
In factories, stationary gas, oil and petrol engines	680,177
For agriculture, stationary gas, oil and petrol engines	98,785
For motor-cars and cycles . . .	750,000
	1,528,962

In the United Kingdom a total of over 1½ million h.p. combustion engines thus existed in the year 1907.

An inquiry made in Germany in the same year showed a total of 351,000 h.p. of stationary combustion engines in operation in factories, and the total number of motor vehicles in use was 27,026, of which about one-half were motor-cycles. The total power of the locomotive petrol engines was not more than 180,000 h.p.

The total power generated by internal combustion was thus:—

	Horse-power.
In factories, stationary gas, oil and petrol engines	351,000
For motor-cars and cycles . . .	180,000
	531,000

In Germany a total of 531,000 h.p. combustion engines existed in 1907, a little more than one-third of the similar power of the United Kingdom.

The census of production of the United States of America for 1909 shows that there were in use 1,299,021 h.p. of gas and gasoline engines for the stationary work of manufactures and mines.

Nearly 115,000 motor-cars were produced in that year; this, with the vehicles in use, required engines of a total of about 1·2 million h.p.

Total combustion power for the United States was certainly not short of 2·5 million h.p.

The internal combustion power in these three countries during 1907 and 1909 was:—

		Million horse-power.
1909.	United States of America . .	2·5
1907.	United Kingdom of Great Britain and Ireland	1·53
1907.	Germany	·53
		4·56

—over 4½ million h.p.

Allowing for the increase of Britain and Germany from 1907 to 1909, a probable value for the total combustion power of the three nations in 1909 is 5 million h.p.

In 1909 France had 46,000 motor-cars in use of an average of about 13 h.p., or a total of 598,000 h.p.

The power of stationary combustion engines in France is not available, but the four countries show a total of at least 5¾ millions in 1909.

This figure does not include oil and petrol engines used for marine purposes, which probably brings the total up to 6 millions.

In 1909, then, we find at least 6 million h.p. of gas, oil, and petrol engines in the world—a truly great development since 1876.

In the year 1909 America led the world in the power of such engines at work, Great Britain came second, and France and Germany were nearly equal with the third place; and although great expansion has taken place in all these countries, Germany still retains the same relative position—America and England still lead.

In addition to internal combustion all these engines have another feature in common—all compress the working fluid before combustion; some compress an inflammable mixture and fire the compressed mixture, producing a mild explosion with a strictly limited possible rise of pressure; some compress air alone and then mix at the temperature of compression the inflammable gas or vapour and ignite as before; and some compress the air charge so highly that on the injection of oil fuel in a state of very fine spray the heat of compression causes the ignition of the spray as it enters the cylinder—such engines do not produce an explosion; the pressure within the cylinder never exceeds the pressure of compression or the pressure of the compressed air sometimes used to pulverise or disperse the liquid oil.

The engines operated by explosion are called constant volume engines, and those actuated by expansion, due to flame, constant pressure engines. Constant volume and constant pressure define the thermodynamic characteristics of the engines, but the mechanical cycle adopted to carry out in practice the necessary charging, compressing, igniting, expanding, and exhausting operations are varied. Two mechanical cycles are in general use: in one the motor piston and cylinder alternately act as pump and motor, so that four single strokes are necessary respectively for charging, compressing, expanding after igniting, and exhausting; in the other these operations are performed in two single strokes of a piston; air or the charge, however, has to be pumped and lightly compressed by a separate lighter piston or by the front of the motor piston. All existing gas, oil and petrol engines, whether light or heavy, operate

according to one of these cycles—the majority of engines in accordance with the four-stroke system.

This feature of compression before ignition is necessary in order to provide an economical engine expanding the gases of explosion in the most favourable manner and at the same time producing large power for small bulk. This mode of operation was the invention of an English engineer so far back as 1838. It will be found described in Wm. Barnett's Patent No. 7615 of 1838, where he gives full particulars of a double-acting internal-combustion engine having separate air and gas pumps, which supply a charge under light pressure to a motor cylinder, in which there acts a piston overrunning a large port in the middle of the stroke. The charge displaces the products of the previous explosion, and is compressed by the return of the piston into a combustion space left at the end of the cylinder. Barnett had fully realised the advantages of compression before ignition, and proposed in accurate detail an engine closely resembling modern two-stroke engines. He was the originator of both the compression idea in its present form and the two-stroke cycle of operation.

The first German engineer to appreciate the advantages of compression was Gustav Schmidt, but he did this twenty-three years later than Barnett, in a paper read before the Society of German Engineers in 1861. Schmidt states, criticising the Lenoir non-compression engine: "The results would be far more favourable if compression pumps, worked from the engine, compressed the cold air and cold gas to three atmospheres before entrance into the cylinder; by this a great expansion and transformation of heat is possible."

Million, a clever Frenchman, in his Patent No. 1840 of 1861, shows that he had exceedingly clear ideas of the advantage of compression; he evidently considers himself as first to propose its use in a gas engine, apparently unaware of the existence of Barnett's engine which I have just described. He claims the exclusive right to use compression in the most emphatic language. One engine described is exactly what Schmidt asked for. Separate pumps compress the air and gas into a reservoir, from which the movement of the motor piston, during a portion of the stroke, withdraws its charge under compression. Ignition is accomplished by the electric spark, and the piston moves forward under the high pressure produced.

He also describes a compression engine in which the motive cylinder is made longer than necessary, in order that the piston shall always leave between it and the end of the cylinder a space such as one-fourth or one-third of the volume generated by the motor piston. Here he resembles Barnett and the modern internal-combustion engines.

M. Alph. Beau de Rochas, a brilliant Frenchman, in a remarkably clever pamphlet published in Paris in 1862, discusses the conditions of economy in gas engines using compression with reference to volume of hot gas and cooling surface to which they are exposed.

He states that four conditions are necessary in order to obtain the maximum economy in a compression explosion engine:—

1. The greatest possible cylinder volume with least possible cooling surface;
2. The greatest possible rapidity of expansion;
3. The greatest possible expansion; and
4. The greatest possible pressure at the commencement of the expansion.

He therefore reasons that a large cylinder is necessary, and the time of exposure to cooling should be as short as possible and piston speed high.

He considers that the sole arrangement capable of meeting the conditions is a single-cylinder engine having the following series of operations:—

1. Suction during an entire out-stroke of the piston;
2. Compression during the following in-stroke;
3. Ignition at the dead point and expansion during the third stroke;
4. Forcing out of the burned gases on the fourth and last return stroke.

The ignition he proposes to accomplish by increase of temperature due to compression. This he expected to do by compressing to one-fourth of the original volume. He also proposes a double-acting engine of the same type with piston rod and stuffing box.

Beau de Rochas' proposal had to wait for fourteen years before it was put into successful practice. The late Dr. N. A. Otto, of Cologne, succeeded in overcoming the practical difficulties in the year 1876, when he produced the first commercially successful gas engine utilising the idea of compression before ignition, first proposed thirty-eight years before by the English engineer Barnett, applied by the means of the cycle of operations due to Beau de Rochas. The modern four-stroke engine was thus the outcome of the English, French, and German brain. The world, however, remains deeply

indebted to the late Dr. Otto, whose ability and pertinacity, applied at the crucial time, produced an engine which marks an epoch in the advance of internal-combustion motors. Dr. Otto deserved his success; he had fought long and hardly for it. He was born at Holzhausen in Nassau in 1832; he began his work on gas engines in 1854 at twenty-two years of age; attained his first success—the Otto and Langen engine already referred to—in 1866; and made his epoch-making advance in 1876. He applied his whole life to the study and development of the gas engine, and died in the year 1891 at the age of fifty-nine, after thirty-seven years devoted to the problems of internal combustion.

Although in 1861 Schmidt in Germany and Million in France described compression engines with separate compressing pumps, no two-stroke engine appeared in public till 1879, when I exhibited my first compression gas engine at the Kilburn Show of the Royal Agricultural Society of England. This engine was patented in 1878 (Patent No. 3045). It had two cylinders, a pump and a motor, each of 5 in. diameter by 8 in. stroke. The pump compressed a mixture of gas and air into a reservoir at the full pressure required; the mixture was admitted to the motor cylinder during the first part of its stroke, cut off by valve and ignited by an incandescent platinum igniter, the piston driven forward by the explosion, and after expansion the return stroke of the piston discharged the exhaust gases. This engine was heavy for its power, and it was subject to the difficulty of back ignition into the reservoir, so that it was not placed on the market. The engine gave three brake-horse-power, however, for many months, and it is believed to be the first compression engine ever run giving one impulse for every two strokes of the motor piston.

The engine best known by my name was patented by me in 1881 (No. 1089 of 1881). It resembled Barnett's of 1838 in compressing within the cylinder and giving one power impulse for each double stroke; but it differed in applying exhaust ports at the out end of the stroke overrun by the piston to time exhaust and charging. It further differed in coupling the pump or displacer cylinder to the main crank shaft, instead of driving at twice the number of revolutions by gear wheels.

At the time when I was inventing, designing and experimenting with two-stroke engines in Glasgow, a Northumberland man, the late Mr. James Robson, was busily at work on compression. His first patent is dated 1877, No. 2334. It describes an engine of the non-compression type; but he produced a two-stroke engine with compression, under patents dated 1879 and 1880. Messrs. Tangye, of Birmingham, produced an engine with Mr. Robson, which was first exhibited in public by them at the end of 1880. In this engine the front end of the cylinder was enclosed and used as a pump to force a mixture of gas and air into a reservoir at a pressure of about 6 lb. per square inch above atmosphere; the piston over-ran ports in the cylinder, but the exhaust was not timed by it; a separate valve was used which controlled the exhaust.

Siemens in 1861, and Brayton in 1873, had proposed constant pressure engines, in which the front end of the cylinder was used to compress the charge which was utilised on the other side of the piston to produce power by combustion and expansion; but Robson was first to propose the use of the front to compress lightly the charge for the compression engine of the explosion type.

The two-stroke or impulse-per-revolution engine was thus the result of the work of the English engineer, Barnett, 1838; the French engineer, Million; and the German engineer, Schmidt, in 1861; and British engineers, Clerk and Robson—Clerk by his 1878 and 1881 engines, and Robson by his 1879 and 1880 engines.

Mr. Robson's son, Mr. James Robson, of Messrs. Tangyes, Ltd., published an interesting booklet last year describing his father's early work, from which it appears that Robson experimented with gas engines of different types from the early date of 1855, and he rightly claims priority for his father as the inventor of one type of two-stroke engine—that in which all the pumping and motor actions are performed by one piston in a single cylinder.

Undoubtedly Mr. Robson was very early in the field, and his work was most meritorious; but the existence of Barnett, Million, and Schmidt prevented any later inventor from claiming the whole idea of impulse-every revolution. Robson and Clerk both invented modifications which made the two-stroke idea practicable; but as the four-stroke cycle had been invented by Beau de Rochas, so the two-stroke idea was likewise proposed by the earlier inventors.

Messrs. Sterne & Co., engineers, Glasgow, built and sold large numbers of Clerk type two-stroke engines, and Messrs. Tangyes, of Birmingham, a large number of Robson engines.

The test of use and time, however, proved the four-stroke engine to be best adapted for most purposes, and by far the largest numbers of internal-combustion engines in existence operate according to this cycle.

Many of the larger gas engines in Germany and America operate upon the Clerk modification of two-stroke compression engine as adopted by Messrs. Kœrting, of Hanover, and their licensees. In the inquiry made in Germany referred to already, it was proved that 260,000 brake horse-power was produced in that country in the year 1907 by four-stroke engines, and 91,000 brake horse-power by two-stroke engines.

A modification of the Robson two-stroke engine was made in England by Mr. Day in 1891, in which a crank case was used as the pumping chamber, and the piston, by means of three cylinder ports, performed all the necessary valve operations. This form of engine is largely adopted in America for launch propulsion; some motor-cars also used it. An increasing use is being made of two-stroke engines for large gas and oil engines, and this type is now firmly established, and shares the field with four-stroke engines; both have advantages on some points and disadvantages in others.

The engineering and commercial development of the four-stroke engine proceeded simultaneously in England and Germany. The Messrs. Crossley, of Manchester, constructed many thousands of these engines, and as the result of study and experience they made numerous improvements of an important kind. The German works, the Gasmotoren Fabrik, of Cologne, under Dr. Otto, continued the work in Germany, and this company also constructed large numbers of engines; and Dr. Otto, Herr Daimler, his works manager, and others produced important modifications and improvements. All the numerous engine works established on the Continent and in America were enabled to work successfully from the experience produced in the first instance by these two firms. The early development of the engines, however, was seriously hampered by an erroneous theory of the action of the explosion under compression held by Dr. Otto and supported in Germany by a physicist even so learned as Dr. Slaby. This erroneous theory also received support from several English scientific men of eminence. According to Dr. Otto, all gas engines previous to his four-stroke motor of 1876 obtained their power from the explosion of the homogeneous charge of gas and air. By this explosion excessive heat was supposed to be evolved, and the pressures produced rapidly fell away and the excessive heat was rapidly absorbed by the enclosing cold walls. This, Dr. Otto said, caused great loss and gives very wasteful engines. The two methods were open to obtain better economy:—

1. By using a very rapid expansion so that the heat had but little time to be dissipated;

2. By using slow combustion, that is, by causing the inflammable mixture to evolve its heat slowly, so that the production of excessive temperatures and pressures was avoided.

The Otto and Langen engine, with its shooting piston, obtained its economy by long very rapid expansion; the Otto four-stroke compression engine was supposed to obtain its economy by a gradual evolution of heat throughout the stroke, produced, Dr. Otto thought, by the stratifying of a charge of gas and air in the cylinder. This false theory of the action of compression, if persisted in, would have blocked all improvement in power and economy upon the very moderate results obtained in 1876. The greater part of the credit of working out the true theory of operation of compression gas engines falls to Great Britain. A paper read by Clerk before the Institution of Civil Engineers in London early in 1882 discussed the theory of compression, and proved definitely and numerically the relative improvement in thermal efficiency to be expected by using compression previous to ignition. That paper, in fact, established the air standard of efficiency for internal-combustion motors. This was taken up later by Dr. Amie Witz, of Lille, and the whole subject was dealt with fully, so far as the knowledge at that time allowed, in a book published by Clerk in London in 1886. In that year also a paper was published at the Institution of Civil Engineers, also by Clerk, giving the results of investigations upon the different maximum pressures produced by mixtures of coal gas and air ignited at atmospheric pressure within a large closed vessel. In that paper the whole subject was dealt with quantitatively, and it was proved that the conditions of economy were, so far as explosion is concerned, due to the use of moderate temperatures produced by homogeneous explosive mixtures; stratification was proved to have nothing whatever to do with economy. Other investigators took up the work of Britain, and explosion experiments with various mixtures and pressures of gas and air were made both in American and German colleges which corroborated Clerk's results. The modern improvement

of thermal efficiency flows from a knowledge of the true theory of compression, and by the aid of abstract knowledge the indicated thermal efficiency in commercial internal-combustion motors has risen from 16 per cent.—Otto's results in 1876—to 35 to 40 per cent.—esults of high-compression engines used to-day. A very important portion of the work of investigation of the conditions of gaseous explosions is due to the Gaseous Explosions Committee of the British Association. That committee was formed at the Leicester Meeting in 1907, and a great deal of important experimental work has been accomplished by its members in the nine years which have elapsed.

Notes on experimental investigation into explosion temperatures; rates of temperature rise and fall; dissociation of steam and carbonic acid; radiation during chemical combination and after; variation of specific heat of air, nitrogen, carbonic acid and steam with increase of temperature; causes of varying rates of inflammation; comparing closed vessel explosions with engine cylinder explosions, temperatures of cylinder walls and pistons; composition of exhaust gases, suction and exhaust temperatures; variation of heat loss during expansion at differing gas densities; internal energy of gases at high and low temperatures, and many other matters have been submitted and discussed by Callender, Clerk, Coker, Dalby, Dixon, Petavel, Harker, Hopkinson and Watson.

Independent chemical work, too, has been accomplished by Bone, Dixon and Smithells, while Burstall has made additional investigations on temperatures. The properties of the working fluid of the internal-combustion engine at high and low temperatures have thus become known to the engineer and inventor to assist him in making further departures intended to increased the power of those motors to compete more and more with the very large steam turbines and reciprocating steam engines of to-day.

Five reports have been published by the British Association summarising these separate investigations.

Germany has also carried out some investigations, principally at the Reichsanstalt, in Berlin. On the whole, however, the German scientific work on this subject is much inferior in importance to the British. Most valuable French work has been also done from Regnault to Mallard and Le Chatelier, Berthelot and Witz.

Some American work has also been performed, but undoubtedly the English work on the nature of gaseous explosions dealing with questions of varying specific heat, rate of heat loss to walls, effect of polished inner surfaces, radiation effect, and the discussions on dissociation have proved of vital importance to the science of this subject. Curiously enough, the German scientific men are far behind in the theory of these motors, although their practical constructors have done excellent work, even with most erroneous ideas of the nature of the forces with which they were dealing.

The stationary internal-combustion engine industry grew very rapidly in England, and as will be seen from the figures already given, the German industry in 1907 was smaller than the English industry, and just before the war it is believed that the proportion of industrial engine work in England and Germany was practically the same as in 1907. An impression has grown in this country that Germany was more advanced in the application of internal-combustion power than we are here. This is due to the fact that the Germans have devoted much more attention to the large cylinder gas engine and oil engine than the British. English engineers have never been satisfied with the existing line of development of these large cylinder engines. From the scientific point of view they consider that the building of large engines practically without modifications of either thermodynamic or operative cycle was a costly mistake leading to development in a wrong direction. Accordingly in England more attention has been given to multi-cylinder engines than in Germany, the idea being to keep the dimensions of the cylinders as small as possible. By so doing, engines were produced of a greater power for a given weight of metal utilised. British engineers and scientific men are still convinced that other methods must be found of increasing power in internal-combustion engines than mere increase of dimensions of cylinders and massive construction of engine parts as practised in Germany. Undoubtedly a solution will be found which combines high powers with small weights. So far as stationary engines are concerned, cylinder for cylinder, the internal-combustion engine is at a disadvantage in weight for power compared to the steam engines without their boilers. A very large industry has been created in small cylinder engines, but the power unit attained as yet is not sufficiently great to compete with the larger steam engines, especially in the form of steam turbines. Notwithstanding the fact that English makers mainly confine themselves to smaller cylinder engines, it is a mistake to

assume, as is too often done, that the Germans are in advance of us in this line of work, either in practice, industry or science. While in Germany engineers paid great attention to larger cylinder engines, England was busy developing the smaller types adapted to use heavier oils, such as kerosene and paraffin. The first engine to attain success as a kerosene or paraffin engine was produced by Messrs. Priestman, of Hull, in 1885. Mr. Stuart Akroyd, in his patents of 1886 and 1888, described an engine which, in the hands of Messrs. Hornsby, has taken a most important position. In that engine air alone is taken into the cylinder of an internal-combustion engine through an inlet valve, and the combustion chamber is kept separate from the inflowing air by the device of using a chamber of bottle-neck construction, the bottle-neck opening into the cylinder. This bottle-neck combustion chamber is only partially water-jacketed, and one part of its surface can in the first instance be raised to a low red heat by means of a pressure lamp. The oil to be used is pumped into this combustion space during the suction stroke of the engine, but little or no mixture occurs until compression begins. The compression of the air by the piston on the return stroke forces the air charge to mix with the vaporised oil existing in the combustion space mixed with products of the previous ignition. The temperature of the hot wall is so adjusted that when compression is complete or nearly complete the mixture ignites and a moderate explosion pressure is produced. This type of engine is very successful, and is made in large numbers throughout the world. Other methods of operating internal-combustion engines have been experimented upon in this country by many inventors and manufacturers.

One set of experiments made by me possesses special interest. The experiments were made at Messrs. Tangyes' works in Birmingham at the end of 1887 and the beginning of 1888. In this engine the cylinder was charged with air on the two-stroke method which I have already described. The air was compressed into a space at the end of the cylinder, and coal gas was compressed by a separate pump. When the motor piston completed the compression of air, the gas pump forced a jet of compressed gas into the compressed air, and an igniting device was so arranged that this jet ignited as it entered the compressed air. No gas was added to the air until compression was complete. The diagrams produced by this engine closely resemble those of the steam engine—a rise at the beginning of the stroke, constant pressure for a certain forward part of the stroke, then cut off and expansion. The engine, in fact, was as I called it at the time, a flame-injection engine in which explosion was avoided altogether. This engine ran for six months and many tests were made. The explosion engine was held to have certain advantages which prevented this particular type from being put upon the market. Its interest arises from the fact that it was, I believe, the first engine operated by the injection of a flame jet into compressed air within a cylinder. Five years later Dr. Diesel, the distinguished German inventor, began work on an engine in which he compressed air through a range of about twelve. Compressing air to one-twelfth of its former volume sufficiently rapidly, raises the temperature of the air to about 600° C. Dr. Diesel then injected fine oil spray into this highly compressed hot air. The spray at once ignited, and a diagram very similar to the early Clerk diagram was produced, but at a much higher pressure with greater expansion, and therefore much greater economy.

Dr. Diesel was an able engineer of great pertinacity, and he succeeded in working through the great difficulties of this type of engine. It has, as we all know, become a most important feature of internal-combustion work. The Diesel type engines, with their high compression and automatic ignition, used for the first time very heavy oils in a most effective way. The Diesel engine undoubtedly fulfils important purposes in both stationary and marine work where oil can be had. Although it has taken an important place, and will continue to occupy an honourable position, its advocates have rather exaggerated its possibilities. The amount of oil in existence in the world is too small to allow of the future proposed by Diesel enthusiasts. For stationary purposes undoubtedly gaseous fuel prepared from coal or carbonaceous matter will maintain the leading position.

An interesting paper was read by Dr. Diesel at the Institution of Mechanical Engineers in the beginning of 1912, and in the discussion which followed, Diesel most honourably admitted the advantages he himself had derived in producing his engine from the study of earlier English work. Dr. Diesel's fate was a sad one. He worked with the utmost faithfulness and pertinacity from the initiation of his experiments in 1887 until his untimely death in 1913. He was lost, as you will remember, from the steamer "Dresden," on a passage between Antwerp and Harwich on September 29th, 1913.

Notwithstanding his strenuous and useful work he died in great monetary difficulties. The period of existence of his patent in Germany and England was insufficient to enable him to reap any reward for his persevering technical efforts. This has proved the fate of many inventors, and the more important the invention the more likely is it that the term of the patent expires before commercial success is attained. Great departures are made with difficulty, while small changes are easily and rapidly applied. In the early stages of the Diesel engine the inventor was under the impression that he could produce a motor which followed the Carnot cycle in its entirety. Such an engine requires compression to the full temperature necessary for the addition of heat, expansion for a certain distance at constant temperature, and then further expansion to the lowest temperature, the heat discharged being obtained by compression at the lowest temperature. Such a cycle of operations gives the maximum possible efficiency between certain heat limits. Diesel misapprehended the position, and he failed at first to see that the mean pressure obtained in such a cycle was very low compared to the maximum pressure necessary. Thus, with a maximum pressure of 500 lb. per square inch the mean pressure was only 6 lb. per square inch. Such an engine would be, under the assumption, a perfect thermodynamic machine; but unfortunately it would give no power — friction would be too great. Accordingly the claim made by the supporters of Diesel in its early stages to a superior thermodynamic cycle from that of ordinary explosion compression gas engines falls to the ground. As a matter of fact the Diesel cycle has a smaller efficiency for a given compression than the explosion cycle.

Had coal gas been the only fuel possible for internal combustion engines it could not have attained its position of to-day. In providing other gases for this purpose England also led the way. Mr. J. E. Dowson, in 1881, constructed a gas producer, using anthracite, which operated by passing a mixture of steam and air over the incandescent anthracite. The gases leaving this apparatus contained hydrogen, carbonic oxide, some carbonic acid, nitrogen, and a little oxygen; and when cooled evolved on combustion about 160 B.Th.U. per cubic foot.

The pressure gas producer which he first exhibited, operated a Crossley gas engine in the year 1881 at the York meeting of the British Association. The invention of the Dowson pressure producer extended the sphere of these engines in a very material way, and led to the construction of what are called suction producers, operated without steam boilers or pressure blowers. Such producers have been applied very extensively in Britain and all over the world in units of from about 20 to 500 h.p. The suction modification was operated at first in France by the well-known engineer, Benier, in 1894, and the French development was continued in England and in Germany about eight years later.

England, too, led in the use of bituminous fuel producers; the late Dr. Ludwig Mond, of Brunner, Mond & Co., devoted much time and effort to the production of large plants capable of gasifying bituminous fuels. In the larger plants Dr. Mond included devices for the chemical recovery of ammonia and the production of sulphate of ammonia. This work of Mond's has been most important, and many large installations of gas engines are now in operation up to about 3,000 h.p. using gas from Mond plant.

An English inventor, the late Mr. B. H. Thwaite, in 1895 made an important experiment in the application of the waste blast furnace gas to the purpose of power production. His first plants were installed at the Glasgow Iron Works and at Barrow-in-Furness, and the idea was soon taken up at the great Belgian works of Messrs. Cockerill. There the large cylinder gas engine was first developed. About 1900 an engine of 51-in. cylinder diameter was exhibited as applied to blowing for blast furnaces. This engine was the result of the work of M. Delamare Debouteville. This was the beginning of the large cylinder movement on the Continent. It was taken up in Germany by the Deutz Works, Cologne, and by the Oechelhauser Company. America followed, and in England, too, several makers devoted considerable attention to the large cylinder engines. The large cylinder movement has, however, undoubtedly prospered more on the Continent and in America than in this country. The extent of the trade, however, is not very great compared to the trade in small cylinder engines; and it is to be hoped that the efforts of British and other engineers will be successful in producing more powerful engines of less weight and bulk. The present large cylinder engine solution is by no means satisfactory, either to the engineer or to the scientific man.

The leading names in German invention and design are thus Otto, Daimler, Diesel, Oechelhauser, and Koerting.

British work in this line was accomplished by

Crossley, Clerk, Robson, Atkinson, Humphrey, Priestman, Akroyd Stuart, Hornsby, Dowson, Mond and Thwaite.

The four-stroke Otto engine, it will be seen, was adopted in England by Messrs. Crossley, and the two-stroke engines of Clerk and Robson were adopted in Germany by Koerting and Oechelhauser.

Of the German inventors, Otto is by far the most important. Daimler's merit consisted in his appreciation of the fact that a four-stroke engine of small dimensions could be safely run at a high speed of rotation; and his little petrol motors, from their relatively light weight and high power, were rapidly adapted by Germans, French and Belgians to the purpose of motor-car propulsion. England, unfortunately, was hampered by an absurd law which required mechanically-propelled vehicles to be preceded on the road by a man carrying a red flag. This red flag Act was not repealed until 1896, so that after that date Britain rapidly gained headway in the construction of the very small cylinder petrol engine, and by its designers and scientific investigators shared fully in the modern development of the motor-car and the aeroplane. The aeroplane became practicable by the genius of the brothers Wilbur and Orville Wright in the United States in the year 1906. They were the first successfully to apply a petrol engine to a mechanical glider. America and France led the way with the aeroplane and the modifications of engine required for aeroplanes until 1909, when the Government Advisory Committee on Aeronautics was started, and the same year saw the beginning of the Royal Aircraft Factory. Another body, the National Physical Laboratory, in conjunction with these two institutions, made numerous experiments on the different factors required in flight. The co-operation of the three bodies in conjunction with the manufacturers of Britain resulted in the highly successful British aeroplane of to-day.

The industry devoted to stationary gas engines, oil engines, and petrol motors in Britain is now very large. An indication of the relative development in England and Germany is given by the comparison, by a well-known Belgian consulting engineer, Mr. R. E. Mathot, of the production of the Gasmotoren Fabrik Deutz and its licensees in Germany with the production of Messrs. Crossley Brothers, Ltd., of Manchester, up to the year 1909. The German firm up to the end of that year had completed altogether 410,098 h.p. of stationary gas engines. The English firm had built 1,020,230 h.p., and this formed but a small part of the output of Britain. From this it must be evident to you that, acting in our own independent manner, Britain has accomplished a large share of the work of the development of the modern internal-combustion engine, both in design, construction, commercial manufacture and development of scientific knowledge. In some fields more work has been done in Germany, in others more in Britain.

So far I have discussed only the development during the modern period, that is, since 1876, but an earlier examination shows that as usual English inventors were very much alive to the necessity of improving the means of obtaining motive power. England and France in the early stage were at work long before Germany. This even the German text-books acknowledge. In an important German work, written by a well-known German engineer, Herr Hugo Güldner, and published in 1903, I find the list of early inventors as follows:—

1791. John Barber, English Patent No. 1833.
1794. Robert Street, English Patent No. 1983.
1801. Lebon, French Patent No. 1799.
1823. Samuel Brown, English Patent No. 4874.
1833. Wellmann Wright, English Patent No. 6525.
1838. William Barnett, English Patent No. 7615.
1841. James Johnston, English Patent No. 8841.
1842. Drake, English Patent No. 562.
1852. Christian Reithmann, experimental four-stroke engine built in Munich.
1854. Barsanti and Matteucci, English Patent No. 1655.
1858. Degrand, French Patent No. 21301.

It will be observed that German industry appears under the name of Christian Reithmann for the first time in 1852. There are other early English inventors who do not appear in the patent lists. Professor Farish, Professor of Physics in Cambridge University, described an engine of the Lenoir type and showed a model working upon his lecture table as early as 1817. The Rev. W. Cecil, of Cambridge, produced an interesting atmospheric gas engine in 1820, and read a paper fully describing it before the Cambridge Philosophical Society in that year.

From this examination it will be seen that the internal-combustion engine, like all great inventions, is the result of a long-continued struggle, and much thought and ingenuity, the outcome of the work of men of many nations.

It is indeed rare to find an invention which can be considered as entirely novel. A search through the records of the past invariably shows tentative efforts to produce a given result. The early efforts always failed, partly from want of fundamental knowledge—in the case of the gas engine, ignorance of the properties of gaseous explosions—and partly from the lack of engineering means of carrying inventions into practicable effect. It is one thing to conceive an idea and quite another matter to carry it into effect in actual operative iron and steel. In the early days of engines constructive appliances were exceedingly imperfect; and, accordingly, we find James Watt rejoicing when he gets a cylinder bored sufficiently true to prevent the passage of a coin between the cylinder and the piston at any point of the stroke. Great work had to be done, and progress in machine tools made before it was possible to bore cylinders with the accuracy required in modern gas and oil engines. Progress is now more rapid on the constructive side, because machine tools are capable of an accuracy measured in thousandths of an inch, and also because of advancing knowledge of the nature of the working fluid, flame, which acts in the interior of those cylinders. The advance, too, of thermodynamics and the better understanding of limits of efficiency prevent inventors from following false paths. Accordingly we may expect further rapid advance in these motors during the next decade.

In this great subject, as in others, we have a right to be encouraged by the story of past effort and the realisation of the present, to look forward to a future in which Britain will perform her full share in the work of development and production. Broadly, development has been great and general, and the field of the reciprocating steam engine has been effectively invaded for both stationary and locomotive purposes on land and water. The steam engine in its various forms, however, still supplies much the largest proportion of motive power. The United Kingdom had stationary engines for manufactures and agriculture in 1907 of about 10·8 million h.p.; the United States had in 1909 about 23¼ million h.p., similarly mostly steam engines. Of this, in Britain, internal-combustion engines gave about 6·4 per cent. and America, about 4·2 per cent. The engines on the ships of the world have a power of about 24 million h.p., a very small proportion internal combustion. The younger engineer of to-day has a huge field of effort open to him, and he will need all the scientific and practical knowledge available to fit him for his task. His position is enviable compared to that of the pioneers, and his progress should be rapid and great. The older combustion engineers have justified their faith and earned an honourable position among the workers of the world.

The fate of the British Empire in the future depends upon the scientific engineer; our present existence as a free nation depends upon our sailors and soldiers; but the more distant future is subject more to the efforts of engineers than to the labours of war or politics.

DISCUSSION.

THE CHAIRMAN (the Hon. Sir Charles A. Parsons, K.C.B., LL.D., D.Sc., F.R.S.), in announcing that the discussion was open, said the paper was a thoroughly sound one on a very difficult subject. It was very comforting to hear Dr. Clerk say that Britain had been in the forefront of gas engine developments, and that there was a larger proportion of gas engines in England and America than in Germany. The question of the large cylinder versus the small cylinder was a subject of very great discussion in this country about two years before the war. The Germans believed that the large cylinder engine was the best type, and some said that we were very much behindhand, and that British engineers and British workmen were incapable of making a successful large gas engine. But the experiments of scientists like Clerk, Hopkinson and Dalby showed that in the large cylinder the heat transmitted to the walls was very much more intense than in the small cylinder. In fact, other things being equal, the heat varied roughly as the square root of the dimensions of the cylinder. Therefore, in a certain size of cylinder, say 200 h.p. or 300 h.p., the heat became so intense that no metal would stand it. The surface of the metal was heated to such an extent that it was compressed beyond its elastic limit, and on cooling it was submitted to a tension beyond its elastic limit, so that hair cracks made their appearance all over the surface, and eventually the crack went right through and the cylinder burst. Steel was worse than cast-iron in this respect. Thus the Germans were wrong as regards the large cylinder, and the English, who were conservative, took the right course, and did not go in to any extent for large cylinders. Further, our experiments showed that the weight per horse-power increases very rapidly as the cylinder increases beyond a certain small size, so that the only way to get a very light engine of large power was to have a great number of small cylinders—in other words, a multi-cylinder engine—and collect the power either by gearing or any other means on the

shaft to be driven. That had not been carried out to any extent in ships, and in this direction, undoubtedly, there was a field open to the engineers.

PROFESSOR E. G. COKER, speaking with reference to the Gaseous Explosions Committee of the British Association, said Dr. Clerk had mentioned that the Committee had been working for nine years, but he did not say—he could not very well have done so—that all through those nine or ten years it was he who had been the inspiring influence. Dr. Clerk had gathered together a number of people interested in the gas engine, both engineers and chemists, and kept them all very busy for a good many years working on different problems, the nature of which he had indicated, until the outbreak of the war, when the Committee was not able to continue the activities it was then engaged upon. All the members of the Committee, however, hoped that after the war the Committee would carry on its work as before. There was one point concerning which Dr. Clerk would do the audience a favour if he would say something upon it, and that was what had happened in regard to the gas turbine since, he believed it was, the Leicester meeting of the British Association. At that particular time they had been promised a paper by a German engineer on the 1,000 h.p. gas turbine, which was going to be a great revolution on anything that had been done before. They had been promised some very high efficiencies; but the paper did not arrive, and he did not remember hearing anything about it since. He believed some experiments had been made later, and would be glad to hear what progress had been made since that time.

MR. A. EVANS, referring to the Hornsby or Stuart Akroyd engine reminded the author that in describing this he said that the oil was injected into the combustion chamber while the air was being drawn into the main cylinder. He was under the impression that, although that was the practice in the ordinary Hornsby engine, at the beginning of the Stuart Akroyd invention the oil was injected into the cylinder at the moment of highest compression. In other words, Stuart Akroyd had anticipated what was now known on the market as the semi-Diesel engine. Another point was whether Dr. Clerk had not made a mistake when, in speaking of the Daimler engine, he said that the governor worked on the exhaust valve and kept the valve open when it wanted to cut the engine out again and otherwise let it function in the usual way. He was under the impression that that valve was kept closed.

MR. W. L. OAKDEN asked which internal-combustion engine had attained the highest efficiency, and how that efficiency compared with the best efficiency of any other kind of engine.

DR. DUGALD CLERK said he had had much pleasure in working with Professor Coker and the other members of the British Association Committee. They had been able to carry out many experiments and were proud to find they had discovered many things which the Germans had failed to do. With regard to the gas turbine, Professor Coker was referring to the Holzworth turbine. At the Dundee meeting of the British Association he had been asked to give a short note to the Engineering Section on the gas turbine. In connection with that he asked Herr Holzworth, who said he was coming to the meeting, to give some of the results obtained with his 1,000 h.p. gas turbine. He also asked him if he would answer a few questions which he sent him, concerning efficiency, total power, etc. Just before the meeting he got a wire which gave a much lower efficiency and much lower power than had ever been given before in the published information on the subject, and it was quite evident that in 1912 the experiments were a failure. He had heard since that greater success had been obtained, but on the cycle they were operating with in 1912 they could not possibly equal the efficiency of the steam turbine. People seemed under some misapprehension on the matter of the gas turbine. It was not the faintest use designing such a machine unless some of the advantages of the internal-combustion engine were obtained. The great advantage of the internal-combustion engine was that a higher thermal efficiency could be got than by any thermodynamic method yet discovered. The steam turbine had made marvellous progress, but efficiencies were not high efficiencies from the thermal point of view; they did not equal those of the internal-combustion engine. If a combustion turbine were made giving an efficiency something like that of the steam turbine, it was no use attempting to put it on the market, because the steam turbine had practical advantages. For instance, the temperature conditions were very much easier, whereas the temperature conditions of the gas turbine were very onerous. So far as he knew, the gas turbine had not yet succeeded, although it might do so in the future. As to the method of injection in the Hornsby oil engine, he was called in to test the Stuart Akroyd engine at a very early stage, and that was an engine in which the oil was injected during the suction stroke, and compression took place and the ignition occurred exactly as he had described it. There had been attempts to work the other way, but, so far as practical matters were concerned, they were a failure. There was a good deal of misapprehension about this question of the injection of fuel into air, and a great many people claimed the origin of the Diesel engine. As a matter of fact there were many specifications describing the exact operations of what Mr. Stuart Akroyd called the injection of fuel into the air. One was a Liverpool inventor who was some years before Stuart Akroyd, and long before Diesel. There was nothing new in it, and there were many patents in which the compression was accomplished with air only, and the heat of the walls of the cylinder was sufficient to cause

ignition. Where they all failed, and indeed where Diesel himself at first failed, was in realising the necessity of producing intensely as fine spray, the fuel required. Dr. Diesel had told him that his first experiments were a complete failure because he had not a fine spray. He worked his engine, and could not get a single ignition, until one day he got a terrible explosion and blew the top off his cylinder, and was very much encouraged. That led him to study some of the earlier work, and he discovered that the fine spray was the main point. In none of the engines before Diesel had that been appreciated. As far as he knew, the first engine to work with flame injection was his own in 1887; but even then the economy was not equal to the ordinary explosion, but the Diesel idea was to get compressed air hot enough to ignite the finely-sprayed fuel. Diesel certainly succeeded in using a heavier fuel than could be used in other types. The suggestion with regard to the valve of the Daimler engine was correct. The valve was kept closed. As to the efficiency of internal-combustion engines, there was nothing to choose between the Diesel and the ordinary explosion engine in the matter of brake thermal efficiency. If indicated thermal efficiency was disregarded, it would be found that brake thermal efficiencies of the order of 30 or 31 per cent. were obtained, but the indicated efficiency was increased because the compression of the air for the spray producer was never taken in, and Dr. Diesel himself at the Institution of Mechanical Engineers admitted that the German method of calculation was wrong and gave too high an efficiency. With the Diesel engine the brake efficiency was the true efficiency. The mechanical efficiency of the Diesel engine was generally exceedingly low, something of the order of 75 per cent. against 86 per cent. in an ordinary combustion engine.

A hearty vote of thanks was accorded Dr. Clerk for his paper.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

State Wool.—The acquisition by the State of the season's supply of British home-grown wools, representing about 122,000,000 lb., is a small transaction by comparison with the purchase of probably 700,000,000 lb. forthcoming from Australia and New Zealand during this season. The bargain may be estimated at £40,000,000 cost price, for wool which at market price should be worth £50,000,000. Of the several lights in which the operation might be regarded, the most important is evidently the Imperial one, and the purchase marks a notable development in the husbanding of the resources of the Empire for the purposes of war. Control of the use, destination, and price of the material is firmly established, and the profits in excess of a liberal increase upon pre-war prices are diverted into the public purse and are shared between the Governments concerned. Fine and medium wools are grown elsewhere within the Empire, notably at the Cape, with some in Canada and the Falkland Islands; but even if these were not acquired an effective hold of the Imperial wool resources would have been taken. The South American clip is the sole large outside supply of good wool. The United States and Russian clips are normally absorbed in local consumption, and the coarse wools of Asia stand on a footing of their own.

Control and its Inconveniences.—State control is not without practical inconveniences, several of which have been felt by those handling home-grown wools under Government supervision. Delays increase pending the appointment and satisfaction of officials, much redundant book-keeping has to be performed, uncertainties prevail and points of friction arise in carrying out the formal instructions. The distribution does not get itself done in a swifter, smoother, and more accomplished manner than hitherto, even though the officers selected are practical men of the trade, and numerous parties are left with a sense of grievance. All this was of inferior account so long as the difficulties were confined to a relatively small part of the supplies; but it would be decidedly unfortunate if the troubles were transferred to the main body of the wool business. The industrial misgivings will not disappear until the Colonial wool is coming forward punctually and freely, and until minds are relieved on the subject of contracts which have been entered into in oblivion of the new control.

Costly Cotton.—The control exerted over wool prices is obviously related to the fact that the Government, on account of itself and partners, is the principal purchaser of manufactured woollens and a buyer of probably 100 million yards a year. Much debated measures have been taken also to moderate the prices of such raw jute as is required for official contracts, and the State has its thumb upon the price of flax. Cotton, which is not to any great extent produced in British countries, has been advancing wildly, until Middling American is some three times the price of the early days of the war, and Egyptian is over 22*d.* per lb. These movements have made all more cheaply bought cotton more saleable, and have contributed to the profits of working, but they bode trouble in the end. Efforts to put down speculation in Egyptian cotton have been made in the Liverpool market, and suggestions are heard of the desirability of official intervention to limit cotton prices all round. The Board of Trade has unquestionably powers under the Defence of the Realm Act to interfere in other markets than foodstuffs, but in two salient respects the case of cotton differs from that of wool and jute.

Scientific Progress.—To judge from current discussion, there remain those who find it impossible to imagine how material improvements in existent practice can be wrought. Close application to scientific research will perhaps show the way, and it is satisfactory to know that the preliminaries to new research are quietly continuing. Definite proposals are being drawn up, and their object is to improve understanding of the changes which take place in course of the processes to which goods are subjected. Given more knowledge, it is always possible that more expedients can be used, and textile practice bristles with actions which are only imperfectly apprehended. There are two schools of advocates of scientific investigation; one loud in its promises and eager to gain publicity for its operations, the other firm in its refusals to speak of cash returns, and content to asseverate that any advance that can be made must directly or indirectly be of benefit to everyone. The times are not propitious to research at present for the assistants are otherwise employed, but it is well assured that tasks and salaries will be found for them.

Some Deficiencies.—Manufacturers are not uniformly satisfied with the pitch of mechanical and technical perfection at which they have arrived. A maker of carpets observes that nobody has yet discovered how to make a power-woven Axminster carpet without losing about 25 per cent. of the woollen yarn used as weft. A principal cause of loss is that certain bobbins carrying the weft become exhausted before others, and although it is not impossible to piece together the short lengths remaining, it soon ceases to be profitable to do so, and the material accordingly goes to waste. Then it is represented that a trade which engaged really inventive people would have found a means of obtaining in Wilton-pile the same liberty of pattern and colour as exists in weaving Axminsters. It is pointed out that in weaving Brussels loop-pile, for every one thread brought to the surface four threads of good worsted must pass underneath and serve no purpose that much cheaper material would not fulfil. Then it is urged that the English have still much to learn in making the most of relatively little material. They have not the art of making 1 lb. of wool used for pile present approximately the same appearance as 1½ lb. The removal of these hindrances is not thought easy, but it is held that they ought to be removed.

Applications of Art.—The original designer of textile fabrics was of course a weaver, and tradition tells of hand-loom weavers who climbed to affluence upon the excellence of their own designs. Young designers trained in the mill and technical school get practice in weaving and learn the limitations of their medium. The possibly more artistic outsider, who is moved to submit sketches from time to time, knows less of these cramping influences, and offer effects which cannot be reproduced. Exasperation follows, accompanied by reflections upon the utility of art schools, and the tension is not necessarily relieved by the art-master's assurance that it is a good deal easier to learn technique than to learn to draw. The subject of art-training is eclipsed at present by that of scientific training and research, although it deserves attention. To an unworthy extent the home market has depended upon German and Austrian looms for figured tapestry goods, not necessarily of the most artistic. In lightness and freshness of taste, England has remained consistently behind France, with the result that French manufacturers have earned the wages of their ability in getting more money for an equal outlay in processes and materials. The facts are plain, and it is to be suspected that English firms experimenting in elaborate woven patterns have been deterred by failures which more insight and originality would have converted into successes. In any event, there is more room for brocade and tapestry weaving and for the production of fancy pile fabrics used as trimmings. More looms are being brought into those classes of trade, and their future is at least as much a matter of art as of success.

Gabardine Cloths.—The modern gabardine cloth has little enough relation to the fabrics out of which Jewish or monkish gabardines were made. A gabardine in the current meaning is a raincoat, and cloths suitable for such coats are gabardine cloths. Goods similar in kind were found useful for costumes and dresses, and sell largely, whether under the full name or under the unlovely contraction "gab." cloth. The name was registered as a trade-mark years ago in connection with linen or hempen fabrics, and the veering of its use round to fine, smooth-faced worsteds, cottons and union cloths often dyed to delicate shades, makes an interesting example of inversion. The word has hardly got a definite meaning left, and serves to denote broadly a fashionable type of fabric. Hitherto its use has been more or less by stealth, under menace of an eminent firm of coatmakers who have, however, now abandoned their claim to its exclusive possession.

OBITUARY.

Sir Hiram Stevens Maxim.—Sir Hiram Maxim, who was born at Sangerville, Maine, U.S.A., in 1840, died on November 24th at Streatham. It is really hardly too much to say of him that he was the greatest mechanical genius of his time, and not only was he a most

skilful and accomplished mechanic, but he was gifted with an inventive ingenuity which spread over a very large range of subjects. How wide this range was is well exemplified in his recent autobiography, and cannot be better summed up than it was in the obituary notice in the *Times*:—"One of his youthful efforts was an improved mouse-trap; he did a good deal with automatic gas-generating plants for domestic and other purposes; he invented an automatic sprinkling apparatus for extinguishing fires, automatic steam-pumping engines for supplying houses with water, feed-water heaters, steam and vacuum pumps, engine governors, gas motors, and many other things." There seemed to be almost no purely mechanical problem which he was not capable of solving, and the problems he actually did solve were, as shown by the above extract, numerous and varied.

He will go down to posterity as the inventor of the Maxim gun, which he described in 1885, at the first meeting of the Society he appears to have attended, when he took part in the discussion on a paper upon "The Evolution of Machines," by Professor Hele-Shaw. He had become a member of the Society in 1883, two years after he came to England in 1881. The history of this invention is given not only in his own biography, but has been recalled in many of the obituary notices published in the newspapers since his death. Many who are still alive will remember a visit to the cellar in Hatton Garden, where the gun was fired down a small tubular range dug out below the street. It was also exhibited at the Inventions Exhibition in 1885, though no publication was then made of the fact that the upper part of the heap of sand into which the gun was fired was gradually shaken down by the repeated concussions, and allowed the bullets to pass through into the adjoining gallery, where fortunately they did no greater harm than the destruction of the upper portion of a glass case. The incident, however, led to a cessation of the gun being shown in action.

His next most important invention, though less successful, probably took up more of his attention, and involved an expenditure of more of his money—the development of the aeroplane. His flying machine (which however never flew) was fully described in a paper which he read here in November, 1894, when Sir Richard Webster (afterwards Lord Alverstone) was in the chair. As has been recently recalled, the experimental machine ran upon a track of rails, each rail having above it a duplicate inverted rail, and the utmost the apparatus ever did was to leave the supporting rails and reach the rails above by which it was held down, without actually resting on any support, until by an unfortunate accident the machine was partly wrecked.

Sir Hiram's last visit to the Society—or, at all events, his last public appearance here—was at the reading of Mr. Eric Stuart Bruce's paper on "Mechanical Flight" in 1908, when he made a long and important speech in the discussion, giving some account of his own experiments, dealing fully with the Wright machine, and anticipating to no small extent the course of development and the actual results which have been attained at the present time.

Space would hardly suffice for even a brief reference to his many other inventions. It should not, however, be forgotten that he was one of the earliest to produce a successful incandescent carbon lamp by his invention of depositing carbon on the filament by heating it in a hydrocarbon atmosphere, with the result of producing a more uniform and stronger filament.

For the latter portion of his life he resided permanently in England, and he became a naturalised British subject. It was in 1901 that he received his knighthood.

NOTES ON BOOKS.

CARDS AND CALENDARS. The Medici Society. London, 1916.

In the spring of the present year an exhibition of British Industries was held at the Albert and Victoria Museum. Amongst other exhibits the Medici Society showed some post cards, which were favourably commented on in an "Arts and Crafts" article in the *Journal* last March (p. 378). These "Old Master" post cards were reproductions in colour of a number of well-known pictures, and were said to be "in an altogether different category from the ordinary German coloured post cards . . . highly coloured daubs caricaturing the originals." The opinion was expressed that they were inclined to "err rather on the side of sombreness," and that they were not quite so good as the early productions of a German firm in Milan. This brought out a very interesting letter from Mr. Philip Lee-Warner, which gave an account of the early successes of Hans Hoesch, the artist of the Milan cards mentioned, and his later failures, as well as of Mr. Lee-Warner's own dealings with him. He was a collotype printer, who seemed to have possessed a certain amount of genius, but to have been sadly lacking in other desirable qualities.

Mr. Lee-Warner has now sent some charming specimens of his firm's works, post cards, Christmas cards and calendars, and they certainly show on a small scale the characteristics which have gained for the larger productions of the Medici Society a deserved reputation.

The specimens sent include calendars with reproductions from Raphael, Botticelli, Van

Dyke and other masters; Christmas cards, many of which are from Old Masters, and others are new, and a number of post cards, Venetian and Egyptian drawings in watercolour by Mr. Reginald Barrett. The Venetian cards are reproductions of the very beautiful illustrations contributed by Mr. Barrett to a book on Venice by Miss de Selincourt (Mrs. Zoete) and Miss Henderson, published ten years ago. They are slightly cut down, to bring them into the limits of a post card, but are not reduced. Naturally some of them suffer by the limitation of size, but in other respects the mechanical work of reproduction is as finely done as in the admirable illustrations in the book, and no higher commendation need be desired.

GENERAL NOTES.

SIR WILLIAM WHITE MEMORIAL.—The Committee which was formed with the object of commemorating the late Sir William White's services to the nation in the development of engineering science, and more particularly of naval architecture, has now completed its task. A sum of £3,197 14*s*. 8*d*. was raised by private subscriptions, and this amount has been expended as follows: (1) The provision of a fund for providing a Post Graduate Research Scholarship in Naval Architecture of over £100 per annum, tenable for two years; (2) the erection of a Memorial Panel; (3) a donation of one hundred guineas to the Westminster Hospital. The Memorial Panel has been erected in the entrance hall of the Institution of Civil Engineers. The Research Scholarship Fund has been made over to the Council of the Institution of Naval Architects, who will administer the fund and award the scholarship. The latter is to be known as the "Sir William White Research Scholarship in Naval Architecture."

SURGICAL CATGUT INDUSTRY IN KWANGTUNG.—According to a report by the United States Consul-General in Hong-Kong, there is a considerable quantity of catgut suitable for surgical use produced in South China, some of which finds its way to the United States. The gut is prepared chiefly in Kwangtung Province, and is manufactured from certain high-grade qualities of Hunan silk. It is made usually in two qualities, rough and smooth, and in different-sized strands. The industry depends to some extent upon the nature of the various crops of silk. For example, one factory finds that during the first two months of the season it can turn out only about 40 lb. of each quality of the gut, while in other months it can produce 45 lb. of each. The two principal qualities now sold are quoted at about 22*s*. per lb. c.i.f. United States port, the price varying with silver exchange.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

DECEMBER 6. — C. M. WHITTAKER, B.Sc., "The Coal-Tar Colour Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

DECEMBER 13. — H. WILSON FOX, "The Development of Imperial Resources."

DECEMBER 20 (at 4 p.m.).—A. C. BENSON, C.V.O., Master of Magdalene College, Cambridge, "Classical and Scientific Education."

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

DECEMBER 14. — JOHN AITON TODD, B.L., Professor of Economics, University College, Nottingham, "The World's Cotton Supply and India's Share in it." The RIGHT HON. LORD EMMOTT, P.C., G.C.M.G., will preside.

Dates to be hereafter announced:—

LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

JAMES HARRIS VICKERY, LL.B., "German Business Methods."

CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

OCTAVIUS C. BEALE, "British Arts and Crafts after the War."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel."

SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

ROBERT FORTESCUE FOX, M.D., "British and Foreign Spas."

MISS ELLA C. SYKES, "The Work of the Y.M.C.A. in France."

HORACE M. THORNTON, M.I.Mech.E., "The Industrial Uses of Coal Gas."

W. A. M. GOODE, Hon. Secretary, National Committee for Relief in Belgium, "Relief Work in Belgium."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

January 18, February 15, March 15, April 19, May 17.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

January 30, February 27, March 27, May 1.

HOWARD LECTURES.

Monday afternoons, at 5 p.m.:—

JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." Three Lectures.

LECTURE II.—DECEMBER 4.—Recent developments in knowledge of composition of coal—Coal as a heating agent—As source of power—For domestic heating, etc.—The by-products from coal distillation, their relation to industry, and particularly as raw materials for munitions of war.

LECTURE III.—DECEMBER 11.—Directions in which economy may be realised—Economy in production—The utilisation of small and low-grade coal—Improvements by suitable preparation for market—Economy in use—By-product recovery—Economies possible from centralised systems of power generation: from extended use of carbonised coal, including gas—Low temperature carbonising schemes.

WILLIAM RIPPER, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

ALAN A. CAMPBELL SWINTON, F.R.S., "Electricity and its Applications." Two Lectures.

January 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Howard Lecture.) Professor J. S. S. Brame, "Coal and its Economic Utilisation." (Lecture II.)

Farmers' Club, 2, Whitehall-court, Whitehall-place, S.W., 6 p.m. Annual General Meeting.

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

China Society, Caxton Hall, Westminster, S.W., 3.30 p.m. Rev. G. C. Martin, "China in English Literature."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Mr. I. B. Hobsbaum, "The Production of Nitrate of Soda in Chile."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. R. Farrer, "The Kansu Marches of Tibet."

TUESDAY, DECEMBER 5...Swiney Lectures, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Professor J. S. Flett, "The Mineral Resources of Europe." (Lecture X.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Discussion on paper by Mr. J. B. Ball, "Keadby Bridge." 2. Mr. P. M. Crosthwaite, "Experiments on Earth-Pressures."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. R. C. Bayne, "Stained Glass and its Limitations."

Photographic Society, 35, Russell-square, W.C., 7 p.m.

WEDNESDAY, DECEMBER 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. C. M. Whittaker, "The Coal-Tar Colour Industry."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. C. A. Mitchell, "Copying Ink Pencils and the Examination of their Pigment in Writing." 2. Mr. E. R. Bolton and Miss D. G. Hewer, "Brazilian Oil Seeds."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Dr. R. Piccoli, "Rhythm in English and Italian Poetry."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. F. Oswald and Mr. T. D. Pryce, "Roman Provincial Terra Sigillata, its Evolution and Chronology."

THURSDAY, DECEMBER 7...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. A. C. Chapman, "Spinacidene: a new hydrocarbon from certain fish liver oils." 2. Messrs. C. S. Gibson, J. L. Simonsen and M. G. Rau, "The nitration of 2-acetylamino-3:4-dimethoxy benzoic acid and 3-acetylamino-1:2-dimethoxy benzene."

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Professor W. C. F. Anderson, "Travel Notes in Macedonia."

FRIDAY, DECEMBER 8...Malacological Society, Burlington House, W., 7 p.m. 1. Dr. J. C. Melvill, "A Revision of the species of the Family Pleurotomidæ occurring in the Persian Gulf, Gulf of Oman, and Arabian Sea." 2. Messrs. A. S. Kennard and B. B. Woodward, "On the occurrence in England of *Helicella neglecta*, with notes on the anatomy by Dr. A. E. Boycott, and the radula by the Rev. E. W. Bowell." 3. Messrs. A. S. Kennard and B. B. Woodward, "On the occurrence of *Eulota fruticum* in a living state in Kent."

Shakespeare Association, King's College, Strand, W.C., 5 p.m. Dr. H. B. Wheatley, "The Players' Obligation to Shakespeare and Shakespeare's Obligation to the Players."

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal

Journal of the Royal Society of Arts.

No. 3,342. VOL. LXV.

FRIDAY, DECEMBER 8, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 11th, at 5 p.m. (Howard Lecture.) JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." (Lecture III.)

WEDNESDAY, DECEMBER 13th, at 4.30 p.m. (Ordinary Meeting.) H. WILSON FOX, "The Development of Imperial Resources." The RIGHT HON. THE EARL OF SELBORNE, K.G., G.C.M.G., D.C.L , LL.D., will preside.

THURSDAY, DECEMBER 14th, at 4.30 p.m. (Indian Section.) JOHN AITON TODD, B.L., Professor of Economics, University College, Nottingham, "The World's Cotton Supply and India's Share in it." The RIGHT HON. LORD EMMOTT, P.C., G.C.M.G., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

HOWARD LECTURE.

On Monday afternoon, December 4th, Mr. JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, delivered the second lecture of his course on "Coal and its Economic Utilisation."

The lectures will be published in the *Journal* during the Christmas recess.

CANTOR LECTURES.

The Cantor Lectures on "Vibrations, Waves and Resonance," by J. Erskine Murray, D.Sc., F.R.S.E., M.I.E.E., have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Lectures which have been published separately, and are still on sale, can also be obtained on application.

JUVENILE LECTURES.

A Member of the Council, Mr. Alan A. Campbell Swinton, F.R.S., has kindly undertaken to deliver the Juvenile Lectures this year on "Electricity and its Applications." The lectures will be delivered on Wednesdays, January 3rd and 10th, at 3 p.m. They will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

"OWEN JONES" PRIZES.

Competitions, under the terms of this Trust, have been held annually from 1878 to 1915 in connection with the National Competition of the Board of Education. This competition not having been held in 1916, the prizes were not awarded.

The Council are now prepared to offer six prizes for Designs for Textiles.

Each prize will consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

The designs should be suitable for:—(1) upholstery, including curtains, coverlets, etc.; (2) costume and costume accessories, such as bags and purses; (3) carpets and rugs: (4) tapestry; (5) printed, dyed, and stencilled fabrics; (6) lace and embroidery.

This classification, however, is not exclusive, and designs intended for any textile application not specified will be admitted.

The competition will be limited to students of Schools of Art. No competitor may send in

more than a single design in each of the above classes, but that design may be accompanied by one or two illustrative sketches if necessary. If desired, a sample of finished work executed from the design may be submitted with or in substitution for the original drawing.

Each design must be accompanied by a statement of the intended material (*e.g.* silk, cotton, linen, wool, etc.), the process of manufacture (*e.g.* weaving, lace-making, printing, painting, embroidering), etc., and the contemplated use of the finished material.

Competing designs must be approved by the Master or other authority of the student's school, who must also certify that the design is the work of the student sending it in, and that it has been executed since the date of the last competition. No candidate who has already received an Owen Jones Prize can take part in the competition.

Competing designs must be sent, carriage paid, and labelled "Owen Jones Prize Competition" on the outside, to The Director and Secretary, Victoria and Albert Museum, South Kensington, S.W., between June 25th and June 30th, 1917. They may be delivered by hand on any one of the three days ending June 29th.

The sender must also notify the Secretary of the Royal Society of Arts by post that the design has been sent in, and must enclose stamps or P.O.O. for the return carriage.

No special conditions are laid down as to the size or character of the drawings sent in.

The awards will be made by the Council of the Royal Society of Arts on the recommendation of judges appointed by them.

The Council reserves the right of withholding any or all of the prizes offered, and they will be the sole judges in each individual case of the qualifications of a competitor to receive an award.

All possible care will be taken of the designs, but the Council accept no responsibility for injury or loss.

HENRY TRUEMAN WOOD, *Secretary*.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 6th, 1916; SIR WILLIAM A. TILDEN, D.Sc., Sc.D., LL.D., F.R.S., F.C.S., F.I.C., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Baker, George Percival, Ivydene, Cold Blow, Bexley, Kent.

Heap, Arthur Cecil, Vickers House, Broadway, Westminster, S.W.

Knight, Berkeley, Bradley, Overton Drive, Wanstead, Essex.

Wagner, Orlando Henry, M.A., 90, Queen's-gate, S.W.

The following candidates were balloted for and duly elected Fellows of the Society:—

Chrimes, Charles, Holmcroft, Wilbury Villas, Hove, Sussex.

Hansard, George Albert, B.Sc., LL.M., Auckland, New Zealand.

Lindsay, Stuart Currie, P.O. Box 880 Victoria, British Columbia, Canada.

THE CHAIRMAN said that Mr. Whittaker, the author of the paper, was, by his official connection with British Dyes, Ltd., particularly qualified to speak on the very important matter of the British Coal-tar Colour Industry. The meeting-hall of the Royal Society of Arts was historical in connection with the question of coal-tar colours, for it was there, about fifty years ago, that Perkin delivered his famous Cantor Lectures, in which he gave an account of his discovery of mauve and the colours which immediately followed. The Society had also had since then a good many communications, and most of them, especially those by the late Professor Meldola, contained very serious words of warning to the country as to the serious peril of the textile industries. Since Perkin's first discovery of the coal-tar colours a great many others had been discovered by English chemists, and he personally remembered the magnificent display of crystallised magenta and other things shown in the 1862 Exhibition. He also remembered the talk there was in the early eighties of the enormous dividends that were being paid by Messrs. Simpson, Moore and Nicholson. Everybody now knew how, on the outbreak of war, we were dependent upon Germany for the dyes required by the textile industries, due to the fact that Germany forty years ago succeeded in gradually withdrawing the whole of the industry of making colours from this country. Various reasons had been assigned for this state of affairs, Meldola and others held that considerable blame was attached to the universities of this country for not encouraging the cultivation of the study of organic chemistry. Our failure had also been attributed to indifference on the part of British manufacturers and their neglect of science. Something had also been said about the want of industrial alcohol, and others had pointed to the Patent Laws. All these things might have contributed to a certain extent to the loss of this very important industry, but his own belief was that the various reasons he had set out were only signs

and indications of a much deeper kind of disease. The fact of the matter was that the people to blame in the matter were the British public themselves. In this country, the ignorance as to what science was, and the indifference as to what it did, were notorious, but none the less scandalous. Similarly, the ignorance of the educated British public about scientific men was extraordinary. Only the other day he had been speaking to a highly educated lady, the wife of a judge, and Faraday's name was mentioned. "Oh," said the lady, "Faraday, did not he invent some sort of scale?" She was thinking of Fahrenheit. That was only an illustration of the ignorance of educated people, and particularly those who had been brought up at Oxford. Mention Faraday's name or the name of any of the great scientific people of the past and in most cases you would get no response. It showed that Oxford and Cambridge did not choose to cultivate organic chemistry, and it showed also that the manufacturers of this country had been largely indifferent to the use of science, because so many of them had been brought up in the public schools under the influence of an antiquated and mediæval system of education.

The paper read was—

THE BRITISH COAL-TAR COLOUR INDUSTRY AND ITS DIFFICULTIES IN TIME OF WAR.

By C. M. Whittaker, B.Sc.

When your Secretary honoured me with an invitation to give a paper on the above subject before your Society he realised that such a paper must necessarily contain a certain amount of repetition of matters already freely discussed: such being the case, there is no need for me to apologise for any such repetitions which are necessary in an adequate treatment of the above subject. I have given two similar lectures previously this year, and after each I have been assailed in certain quarters for not answering criticisms passed on British Dyes, Ltd. I therefore wish to make it perfectly clear at the outset that I am not here as an apologist for British Dyes, Ltd., but simply by invitation to give a paper on the coal-tar colour industry, with which I have been intimately connected for the last seventeen years—would that some of those who have discussed this industry had had the same experience! I shall be pleased to answer to the best of my ability any points which may arise in the subsequent discussion, but I must respectfully refuse to answer any questions on the policy of British Dyes, Ltd.

In giving a paper on the British coal-tar colour industry, it is always necessary to explain at the outset that the present national circumstances prevent one entering into details which would be most interesting and illustrative of the present situation. These facts, which may not at present be given, will no doubt be given in due course, when they will redound to the credit of the British industry.

The British industry, founded by the discovery of Sir William Perkin in 1856, experienced a period of great prosperity in its early days, which was followed by a decline for a number of reasons, one of which, in my opinion, was that money was so easily made in the early days that the owners were content to rest on their oars and enjoy the fortunes they had secured. Though the coal-tar colour industry had languished, it had never actually become extinct. It may, however, be asserted that the British industry had sunk to its lowest depths about the years 1898–1900; but from then onward it commenced to recover, till in 1915 its competition was being increasingly felt by the German firms, which, just previous to the war, were subjecting the British firms to a severe price-cutting campaign because the British competition in sulphur and direct cotton blacks was reducing to complete nullity the German conventions in those two classes of colours. This improvement had been brought about by enlightened management, which had gradually and unobtrusively been modernising their works and their methods. Had not this revival taken place the task of building up an industry on a national scale would have been made infinitely more difficult, whilst the panic in the dyeing trades at the outbreak of war would have been gravely aggravated and would in all probability have jeopardised the dyeing of the clothing equipment required by the military authorities. The British firms were a considerable national asset at the outbreak of war; had these firms with their trained staffs and experience not been available, it would have gone much harder with colour consumers. The fact that a private firm like Read Holliday & Sons, Ltd., were in a position to pay a dividend of 10 per cent. for the five years previous to the war, when they faced, unaided, the full weight of the German competition, shows that it was possible for a British firm to make a successful fight against the Germans. It is a favourable omen which is consistently ignored by those critics who are untiring in their gloomy forecasts of failure for the efforts presently being made in Great Britain—professional whimperers, as your Chairman termed them the other day.

I wish to take this opportunity of destroying

some of the fallacies concerning British firms which have too long been current and which still persist in some quarters. For the last fifteen years I have been in charge of the experimental dyehouse of Read Holliday & Sons, Ltd., now merged in British Dyes, Ltd. It was part of my duty to supervise the matching of patterns sent in by customers, to prepare pattern cards and circulars, and to carry out what has been termed "expert" work in the way of visiting customers' dyehouses when desired. During that time 50,000 patterns and samples have passed through the firm's books, and not a single pattern was ever charged for, yet I have heard it definitely stated during the last three months that one of the greatest mistakes the pre-war British firms made was to charge for pattern matching, whilst the German firms matched them free. The laboratories of Read Holliday & Sons, Ltd., were always at the free disposal of those in the dyeing trade who wished to make use of them.

The British firms have also been accused of not issuing pattern cards and circulars. Such an accusation was not true, for not only were they issued in a style comparable with those issued by the Germans, but they were also issued in five languages, viz., English, French, Italian, Spanish and German. I have such a card here.

Here I have a manual which was issued in three languages as far back as 1906. Here you have a pocket manual of dyeing instructions which has run to three English editions; here you have this same book in Italian, and here you have it in Japanese. Yet it is less than twelve months since that the British colour firms were asked in an address before a scientific society why they did not use the language, weights and coinage of the foreign countries in which they sold their dyes.

The British are a remarkable people in the way they depreciate the efforts of their own countrymen. The service of the technical experts of the German firms has been repeatedly mentioned without any similar mention of the service of the British firms. Owing to the relative scale of the operations of the Germans as compared with the British firms, the German experts were naturally more numerous. They also had this fact in their favour, that they were often welcomed where the British expert was not welcomed. What progress could be made by a British expert with British firms who told him point-blank, "We would not use your colour if you gave it us"?

People seem to forget that it was Read Holliday & Sons, Ltd., who bought Schutzenberger and Lalande's patent for dyeing indigo in a hydrosulphite vat, and it was Read Holliday's staff of technical men who introduced it to the British indigo dyers, and they who broke down the inevitable prejudice against the something new, because dyers are a very conservative race. You can still find old indigo dyers who talk about the hydrosulphite vat as the "Holliday" vat.

Let this fact at least be remembered, that the hydrosulphite vat for indigo was a French discovery, not a German discovery, and that a British firm—not a German firm—worked the patent in Great Britain.

Since 1901 I and my staff have gone out to scores of places to help to solve difficulties which have arisen in the application of dyestuffs in practice, to make first dyeings of new colours with which the particular dyer was not familiar, and to look into difficulties which in many instances have been in no way connected with the dyeing, but with the previous stages of manufacture, but which were attributed to the dyes, because the fault only became apparent after the dyeing. We have even supplied one of our staff for a fortnight to keep a dyehouse going owing to a dyer having been taken suddenly ill and there being no competent understudy available. Such expert service is being given at the present day. One of the most recent cases to which we went was to find out the cause of the stains on some cloth dyed with a product of British Dyes, Ltd. We proved to the owner's grateful satisfaction that it was his water-supply which was at fault and not the dyestuff. I could go on repeating these cases *ad lib.*, yet it is always the German experts who are mentioned and never the British expert. Truly it is time this fallacy received its quietus.

Now let us examine the position at the outbreak of war as regards the coal-tar colour industry in Great Britain. The principal firms engaged were: The British Alizarine Co., which confined its products to alizarin orange, alizarin red, and alizarin blue—it is largely a co-operative company, as its shares are held for the most part by the large consumers of the above products; the Clayton Aniline Co., which had been absorbed by the Society of Chemical Industry, Basle, though it was located in Great Britain; Levinstein, Ltd., Manchester; Read Holliday & Sons, Ltd., Huddersfield. The two latter were limited companies, the

majority of whose shares were held by the respective families.

The outbreak of war suddenly opened the eyes of the consumers of coal-tar colours in Great Britain to the disconcerting fact that they were largely dependent on Germany for their supplies; then ensued a panic which will ever be remembered by the staffs of the British firms, and which panic subjected them to an almost intolerable strain. The country soon realised that the manufacture of coal-tar colours was a pivot or key industry of the highest importance in which Germany held the dominating position, with Great Britain and Switzerland a long way behind. The realisation of this fact was followed by a deluge of articles and correspondence containing the grossest misstatements which appeared in the newspapers and journals, and were a source of no little amusement to the staffs of the British firms. The relative smallness of the industry in Great Britain was, no doubt, the cause of a great deal of the ignorance displayed. The British firms who were carrying on their industry, conscious of their growing strength and quite inured to the cold shoulder consistently turned to them by scientific societies, were suddenly dragged out into the limelight, and received an amount of attention which was embarrassing.

The cardinal facts of the situation, which were in danger of being lost amidst the controversy, were as follows:—

In 1913 Great Britain imported coal-tar colours to the value of £1,946,224, representing 42 million pounds' weight of colour, of which it was estimated £1,800,000 emanated from Germany. It must not, however, be assumed that all this quantity was consumed in Great Britain, because a considerable quantity of colour is bought here for shipment to India, Australasia, South America and other countries. It is doubtful if much more than half a million of capital was employed in the British industry at the outbreak of war; so there you have the basic fact which faced the industry: how to replace an import of £1,800,000 by firms who did not control more than half a million capital. The task was economically and physically impossible of immediate execution in peace times; it was a hundredfold more impossible in the midst of the greatest war of all time.

I will just deal briefly with some of the commonest mistakes which were made with reference to the German coal-tar colour industry during the discussions.

The most frequent mistake was in regard to the amount of capital which the German firms were supposed to employ in their industry. It was freely stated by Members of Parliament and others that the capital of the German industry was anything from one to two hundred millions. This was, of course, absurd; but such statements did not make any easier the task of those who were endeavouring to establish an adequate British industry. The export value of German coal-tar colours throughout the world was, for the year 1913, £11,349,100; add to this the German home consumption at a generous estimate of £2,000,000, making a total turn-over of £13,349,100. The capital of the German industry was £13,500,000 in 1913, showing that the annual production was approximately equal to the capital. Those who talked about one and two hundred millions capital never stopped to explain how a dividend of from 12 to 25 per cent. could be paid on this capital out of an annual turnover of £13,500,000.

Another point with which I wish to deal is the supposed dependency of Germany on outside countries, particularly Great Britain, for many of the important raw materials of the coal-tar colour industry. Such a state of dependency was no doubt existent in the earlier days of the industry; but the modern coke oven recovery plant has largely altered that state of affairs, as the following official figures for the year 1913 of the imports and exports of important raw materials connected with the German industry show. In considering these figures, I would ask you to bear in mind the fact that Germany's export represents the surplus after all the requirements of her home industry have been satisfied. Starting with benzol, toluol, etc., Germany exported 41,287,000 kilos, and imported only 6,709,600 kilos. These figures do not give much of an opening for crippling tactics. To these figures ought to be added 7,264,700 kilos aniline oil and salts exported by Germany against a negligible import of 156,100 kilos.

In 1913 Germany imported 4,155,200 kilos of carbolic acid, and exported 3,601,700 kilos, an adverse balance of, roughly, 500,000 kilos. It was well known by the tar distillers that the Bayer Co. were making an onslaught on the British market with synthetic carbolic acid, which would have effectively reduced the amount of pure carbolic acid distilled from coal-tar in this country. It must also be remembered that Germany will have made

enormous quantities of synthetic carbolic acid during the war, so that under no combination of circumstances could its industry run short of carbolic acid after its experience of production during the war.

Passing on to naphthalene, Germany imported 5,248,700 kilos, and exported 6,151,110 kilos, in addition to 3,106,400 kilos of naphthols and naphthylamines. Again the balance is in her favour.

I now come to anthracene, of which Germany imported 1,286,100 kilos and exported 277,400 kilos. There the balance is decidedly against her, and it is the only important raw product for colour manufacture in which Germany is deficient. It is the starting-point for alizarin and many of the most important vat colours, which latter have added so much to the prestige of the German firms. It must, however, be remembered that bromine enters largely into the constitution of many vat colours, which gives Germany an effective counter against the possible withholding of anthracene.

I now propose to pass on to the handicaps under which the British coal-tar colour industry has been and is labouring.

The Achilles heel of the British industry was the fact that it had been in the habit of buying many of its intermediate products from the Continent. The result was that at the outbreak of war chemists had to work to replace these intermediate products, and suitable plant had to be erected which absorbed a large amount of energy without increasing the immediate output of colour.

One of the greatest handicaps has been the shortage of chemists. On the outbreak of war I doubt if there were twenty British chemists who had had actual up-to-date experience in the manufacture of coal-tar colours on the commercial scale. Of those who had had experience, some had their energies diverted to the manufacture of explosives to the detriment of coal-tar colour manufacture. It was an inevitable result of the close interrelation between high explosives and coal-tar colours. No complaint is made of the diversion of this energy, but it requires to be stated as one of the definite handicaps of the industry during war time. There was no reservoir of trained chemists from which to draw, so that university trained men of good theoretical knowledge but no practical experience have had to be taken, and naturally some time must elapse before they become adapted to their new conditions. The outbreak of the war, bringing in its train the enormous demand for supplies of high explosives on a scale hitherto not contemplated, illustrated how closely interrelated was the manufacture of coal-tar colours and high explosives.

As everybody is aware, the two high explosives most largely in use are picric acid (or trinitrophenol) and trinitrotoluol. The latter requires similar apparatus to that which is used for making compounds like nitro-benzol, so essential in coal-tar colour manufacture. The engineering trade has been so much occupied in connection with the supply of munitions that it has been difficult to get delivery of the plant for the necessary extensions. For the same reason there has been a shortage of the skilled fitters necessary for the erection of the plant and of men to erect the necessary buildings. In fact, the shortage of labour confronts one at every turn. The increases in the prices of copper and lead, which enter largely into the apparatus used in coal-tar colour manufacture, have also added enormously to the cost of such plant.

The life-blood of the coal-tar colour industry is sulphuric acid, fuming sulphuric acid, and nitric acid. It is the misfortune of colour manufacture that it is impossible to make any colour without the use of nitric and sulphuric acids, the latter being required in various strengths of fuming acid from 70 per cent. down to 20 per cent. SO_3 and D.O.V. These selfsame acids are also indispensable for the manufacture of the two high explosives lyddite and T.N.T. It is a matter which admits of no argument that the demand for acids for the manufacture of high explosives must take priority over their numerous industrial uses. In that fact you have the greatest handicap of the British coal-tar colour industry, because, as is well known by every acid consumer, the supply of acids is nothing like equal to the demand.

Amongst the raw or primary products of the coal-tar colour industry the four most important are benzol, toluol, naphthalene, and anthracene. The distribution of one of these products (viz., toluol) is controlled by the Government. The amount of toluol to be distilled from coal-tar has very definite limits, which are relatively small, so that the reason for this control is obvious. Benzol is the starting-point for the manufacture of synthetic carbolic acid, of which so much is being made at the present time owing to the demand far outstripping the production of carbolic acid distilled from coal-tar. This is being converted into picric acid. Benzol is also being used in large quantities for conversion

into dinitrophenol, from which picric acid is also being manufactured.

Naphthalene and anthracene are free markets. The control of one of the chief primary products is, however, a heavy initial handicap on the output of coal-tar products.

Since the commencement of the war I have been in a specially favoured position to diagnose what is passing in the minds of many colour consumers. One common thought which is very prevalent is, "We can understand you not being able to make some of the German specialities such as indanthrene, alizarin sapphirole, etc., nor do we expect you to do so immediately, but we cannot understand you not being able to supply such old colours as Bismarck brown, benzopurpurine 4B, etc., the constitution and method of manufacture of which have been known for so many years." That is quite a reasonable attitude to adopt, and my paper will, I think, show completely the reason. Such colours are not being made freely at the present time, not through inability of British chemists to manufacture them, but owing to the fact that the necessary products are not available, since they are required for more important processes.

The surplus of benzol and toluol which is set free by the Government after all their requirements for explosives purposes have been met has a preferential call on it before it can be used for general colour manufacture. Next to explosives it is the first duty of the British coal-tar industry to supply the various colours required for the varied equipments of the British, Colonial, and Allied Governments. People outside the trade have very little conception of the numerous colours required by the Government; they vary from mordant brown and sulphur black down to methyl violet for typewriter ribbons and soluble blue for ink for the Stationery Office. The huge demand for khaki uniforms required by the military authorities for the equipment of the troops caused a corresponding demand for mordant yellow, brown and green, blue or black. The demand at the outset for these colours was overwhelming. Mordant yellow was very scarce at the beginning, but the demand for this product has now been more than fully met. Seeing that salicylic acid is a constituent of all mordant yellows, and is in turn derived from carbolic acid, you will readily understand why it was scarce. Mordant brown never caused any difficulties, as the supply was and is more than sufficient to meet all requirements. The supply of mordant green has also been very large. Sulphur yellows, browns, and blacks have also been supplied in very large quantities by the British firms for the cotton equipment of the armies, such as cotton webbing, tropical uniforms, trench capes, ground sheets, mosquito nets, etc. Not only have all the British requirements been met, but large quantities of British-made dyes have been used in Australian, Canadian, Belgian, French, Russian, Italian, and Serbian equipments. I do not give these facts as a handicap on the British industry; rather is it intensely proud of its achievements in this direction under such difficult conditions; but I do put it forward as a definite reason why many colours have not been made which would otherwise have been made had not the energies of the British chemists been so largely occupied in producing explosives and equipment colours.

Now let us examine a few of the products derived from benzol and toluol, which are so important for coal-tar colour manufacture, and you will notice how the whole path is beset with a continuous demand for nitric and sulphuric acids. The primary step in the manufacture of coal-tar colours from benzol is to convert it into nitrobenzol. From nitrobenzol one proceeds to aniline oil and aniline salts, which have numerous uses. They are consumed in large quantities for the production of aniline black on the fibre both in dyeing and calico printing. Aniline oil has always been most extensively made in Great Britain, so that the shortage is not due to any lack of manufacturing experience, but mainly due to shortage of acid. It would be tedious to detail all the uses of aniline oil, but it enters into the manufacture of numerous colours, including acid orange, acid blacks, acid reds, magenta, soluble blues, nigrosines, and indulines, whilst in the form of dimethylaniline it is required for the important basic colours auramine, methyl violet, methylene blue, and malachite green; it has also been largely supplied for munition purposes. p-Nitraniline is a very important derivative of aniline obtained with the aid of the inevitable nitric and sulphuric acids. It is consumed in large quantities for the production of para red by the cotton, calico-printing, and paint trades; whilst it enters largely into the production of many important colours, including blacks; it is also extensively used for coupling on the fibre with suitable direct cotton colours; it is, in addition, the intermediate stage in the production of p-phenylene-diamine, which is used in colour manufacture and by the fur trade for producing blacks and browns on furs. Aniline is also the

starting-point for phenylglycine, which is the primary product for one of the two processes used on the large scale for the production of synthetic indigo.

By the alkaline instead of the acid reduction of nitrobenzol, one arrives at benzidine, which is such an important base for the making of a large number of the popular direct cotton colours, such as blacks, blues, greens, violets, oranges, etc.

Benzidine base has been made in this country in normal times, so that here again the present shortage is not due to the inability of British chemists to manufacture the product, but to inability to get a sufficiency of the necessary materials.

Another important product from benzol is dinitrobenzol, which is the starting-point for m-nitraniline, used in wool colours, and m-phenylenediamine. This latter product is of the utmost value in colour manufacture, and enters into the constitution of numerous important colours, such as mordant browns for wool, which have been used in enormous quantities for military uniforms; sulphur browns for cottons, which have been extensively used in the dyeing of all cotton khaki equipments, such as tropical uniforms, cotton webbing, etc.; it is also required for direct cotton blacks and browns, chrysoidine, and Bismarck brown. You will therefore see that this product is in enormous demand, whilst it must not be forgotten that the production of the equipment colours must take precedence of all other colours. This is the explanation why such common colours as Bismarck brown, chrysoidine, and cotton blacks and browns are in such limited supply—again, not due to the inexperience of British chemists, but to lack of the necessary products.

Another product from benzol which is of the highest importance is dinitrophenol. This product is used in the manufacture of sulphur colours, which are consumed in enormous quantities in peace times, and which have been used so largely in Government equipments. It is fortunate for the cotton trade in particular that the manufacture of this important intermediate product and of sulphur colours was so firmly established in this country prior to the war. I do not think it is an exaggeration to say that sulphur colours have been produced in larger bulk than any other class of colour since the war broke out. The production, huge as it has been, has not been enough to satisfy the legitimate requirements of the trade; but here again the shortage has not been due to lack of experience or plant, but solely to lack of material and labour.

It is fortunate for this country that the manufacture of dinitrophenol was firmly established, because it has been used in an alternative process for the manufacture of picric acid other than direct from phenol. It has, therefore, increased the production of lyddite whilst easing the pressure for synthetic phenol.

The amount of phenol distilled from coal-tar being utterly inadequate for the amount of picric acid required by the authorities, large quantities have had to be made synthetically by caustic fusion of sodium benzenemonosulphonate.

Carbolic acid plays a most important part in colour manufacture, and the shortage of this product has been a very great handicap to the colour industry. Phenol enters directly into many colours, and is one of the components of chrysophenine, the direct cotton yellow which is so largely used and has been so badly missed. Ortho-nitrophenol, which on methylation and alkaline reduction yields dianisidine, is another important derivative of phenol, because dianisidine is the base for cotton sky blue, the absence of which has caused much inconvenience to cotton dyers and has caused famine prices to have been paid for any existing stocks of this colour.

Salicylic acid is another important derivative of phenol, both from a medicinal and a colour point of view. It was not made in this country prior to the war, but its manufacture is now firmly established. It is largely used both medicinally and in the manufacture of colours of the highest importance, including fast chrome blacks, reds, oranges, and yellows, also direct cotton reds and greens. The great shortage of these colours has resulted from the scarcity of this product due to the phenol being required for the manufacture of explosives.

The other derivatives of benzol which I propose to mention are resorcinol, made by the caustic fusion of benzenedisulphonic acid; this product enters into the constitution of many direct cotton colours, and also colours of the rhodamine class; another derivative is chlorbenzol, from which are derived some of the fastest chrome colours for wool extant, amongst which may be mentioned the fast chrome blacks which are fast to potting.

In the manufacture of picric acid for explosives purposes, it is inevitable that some is produced which will not pass the Government specifications. This is liberated by the Government for

the purposes of colour manufacture. For the last fifteen years picric acid has played an important part in colour manufacture.

Toluol is of vital importance as a starting-point for colour manufacture, and the restrictions on its use are responsible for the lack of many colours which are absolutely essential for the dyeing trades. Ortho- and para-nitro-toluol are obtained by direct nitration of toluol. From ortho-nitrotoluol tolidine base is obtained by alkaline reduction, and from it are made many direct cotton colours of large consumption. I will content myself with mentioning one, viz., benzopurpurine 4B. This is the reason why such a common and popular colour is not being made in quantity at the present time. There has been a great dearth of direct cotton yellows in the colour market, but the reason is very simple. In peace times there were three main classes of direct cotton yellows used, viz. :—

1. Chrysophenine, which is made from diamino-stilbenedisulphonic acid (a toluol derivative) coupled with two molecules of phenol and the product ethylated; both the products are required for explosives, hence no chrysophenine;

2. Primuline and the fastest class of direct cotton yellows which are derived from dehydro-thio-p-toluidine—these require p-toluidine;

3. The sun yellow, or stilbene yellow class, which require p-nitrotoluol for their manufacture.

The direct cotton yellows form an excellent example of the handicap imposed on the coal-tar colour industry by the diversion of toluol for explosives manufacture. The last two classes of yellow have always been extensively made in Great Britain; so here again the plant and experience is available but not the material.

Toluol derivatives are also required for the manufacture of sulphur blues and greens; this accounts for the limited supplies available, which are insufficient to meet the legitimate demands of the trade. Toluidine also enters into the manufacture of magenta and safranine which are so largely used in the paper trade amongst others, whilst rosaniline is also required for the manufacture of soluble blue so keenly desired by the shoddy trade. Here, again, the experienced chemists and the plant are available, for all these colours were made in Great Britain in peace times, but the material is now lacking.

Dinitrotoluol leads to m-toluylenediamine, which is so largely used as a developer for diazotised cotton blacks and as a component of direct cotton oranges and blacks.

Among the other derivates of toluol which find extensive application are benzyl chloride, benzaldehyde and ethyl and methyl-benzyl-anilines.

I now pass on to the last mother product with which I propose to deal, viz., Naphthalene.

The uses of naphthalene in colour manufacture are multitudinous, but I only propose to deal with those derivatives of major importance. Naphthalene has no limiting restrictions on its sale like benzol and toluol.

Naphthalene has four primary derivatives, viz., a- and b-naphthylamine and a- and b-naphthol, of which the a-naphthylamine and b-naphthol are the more important. a-Naphthylamine has always been largely made in this country. b-Naphthol used to be made in this country, but was not being manufactured on the outbreak of war. The manufacture has now been resumed, and there are several naphthol plants on various scales working in this country at the present time. a-Naphthylamine is the most important constituent of acid blacks, chrome blacks and sulphoncyanines—all three classes of colour of enormous bulk consumption.

Naphthionic acid, the 1·4-monosulphonic acid of a-naphthylamine is largely used in the production of reds, both acid and direct cotton reds; it enters into the constitution of benzopurpurine 4B. Neville and Winther acid, the 1·4-monosulphonic acid of a-naphthol, is also of considerable importance in the manufacture of acid reds and direct cotton blues.

b-Naphthol is itself used to an enormous extent in what are known as the insoluble azo or ice colours, such as para red, naphthylamine claret, etc., whilst it is also largely used as a developer for the ingrain colours on cotton.

The manufacture of large quantities of naphthalene derivatives is not limited by any shortage of naphthalene, but it is seriously limited by the shortage of sulphuric acid and nitric acids.

The following four acids of the highest importance require fuming acid in their commercial production: H. acid, aminonaphtholdisulphonic acid 1 : 8 : 3 : 6, used in acid blacks, cotton blacks, cotton navies and cotton blues: Chromotrope acid, dihydroxynaphthalenedisulphonic acid 1 : 8 : 3 : 6, used in producing a full range of acid reds of easy levelling powers and good fastness to light which by treatment with bichrome are turned to fast navy blues: Gamma acid, aminonaphtholsulphonic acid

2 : 8 : 6, used very largely in direct cotton colours, notably the "BH" class of blacks; Aminonaphtholdisulphonic acid 1 : 8 : 2 : 4, used in the production of bright blues.

The following important acids do not require fuming acid, but may be made with ordinary sulphuric acid: Phenyl peri acid. Phenyl-a-naphthylamine-sulphonic acid, used for sulphon-cyanines; G salt, b-naphtholdisulphonic acid 2 : 6 : 8, and R salt, b-naphtholdisulphonic acid 2 : 3 : 6, used for scarlets, bordeaux, etc.

I have not touched on anthracene and the alizarin colours, the manufacture of which has not up to now been developed in this country, except the manufacture of alizarin orange, red and blue. Here Nature has imposed an additional handicap on their development, due to the fact that practically all the bromine originates in Germany. Bromine is largely used in this branch of colour manufacture. Vat colours (many of which are anthracene derivatives) are the most modern class of coal-tar colours, and with them may be produced shades of excellent fastness to light, washing and bleaching. It is with this class of colour that the modern guaranteed articles, such as casement curtains, shirts, etc., have been dyed. The colour is guaranteed fast under penalties of replacement if it is not so. The German firms have been rightly proud of these colours, and have been very sceptical of the abilities of British chemists to manufacture them; in fact, one German colour chemist went so far as to say that no British firm would make them in ten years. It is therefore with peculiar pleasure that I show you this afternoon a dyeing of the first vat colour made on a commercial scale by British Dyes, Ltd. I show you a test of chloranthrene blue, which is British made indanthrene blue produced at the Turnbridge Works, Huddersfield, of British Dyes, Ltd. British Dyes, Ltd., is particularly proud of this achievement, and it is only the first of a number of others which will from time to time be put on the market.

I have now finished what must have appeared to many but a mere catalogue. However, I have felt it necessary to show the large number of products which are required in the coal-tar colour industry before a start can be made with colour, and to give an adequate idea of the handicaps which the state of war has imposed on the coal-tar colour industry. The shortage of acid in this country is in course of being rectified, and there is no after effect of the war which may be prophesied with more certainty than that there will be an abundant supply of acids in peace time. British Dyes, Ltd., have now got a large oleum or fuming sulphuric acid plant working successfully as well as a large nitric acid plant.

I now propose to show you what has been done by the British firms in the way of satisfying the requirements of the British and Allied Governments in equipment colours.

Those people who are constantly depreciating the efforts of the British firms seem conveniently to forget what has been accomplished in this direction, and never think of putting it down on the credit side of the account.

You may have seen in the scare press that the dyes being supplied by the British firms were not anything like as good as those of the German firms; but I wish to state most emphatically that khaki uniforms dyed with mordant yellow, brown and green of British manufacture are just as fast to light, exposure and wear as any similar cloth that was previously delivered to the British Government dyed with German colours. The British firms have every reason to be proud of their products for this purpose, and the day when it is necessary to stipulate German colours in British khaki specifications is past.

At the top of the khaki boom, when the military authorities were putting extreme pressure on the manufacturers for delivery, one British firm alone delivered 145,000 lb. weight of khaki wool dyestuffs in the month of December 1915. That was a noteworthy effort of which the firm in question was particularly proud, yet according to our critics we ought to stand in sackcloth and ashes and confess our incompetence. Do you wonder that we refuse to do so? Let people contemplate what the manufacture of that large weight of colour meant; then they will realise what British firms have done, and why some other colours were in short supply. Here you have patterns of the three khaki wool colours which have been so largely supplied for the purpose of dyeing the British khaki.

A large quantity of mordant green was supplied by British firms for dyeing the uniforms of the Italian army. Large quantities of mordant yellow, brown and green of British manufacture are, at the present time, being used in the uniform cloth of the Russian army now being made in Great Britain. I show you the two Russian shades here—a red shade and a green shade. Here you have three colours which have been supplied by British firms in huge quantities for the cotton equipments

required by the authorities, such as tropical uniforms, cotton webbing, ground sheets, mosquito nets, etc. The British army is admittedly the best-equipped army in the field to-day. Are the British colour firms to be denied their share of the credit for this pleasing result? When you see at the various railway stations the soldiers coming home on leave, with the mud of the trenches thick upon them, showing under what severe conditions they have been fighting, do their uniforms and equipment look badly faded? They do not, but they are still a good khaki showing that the British-made colours are not incapable of withstanding the severest war conditions.

Few people have a true conception of the amount of preliminary work which has to be carried out in the manufacture of a coal-tar colour. Here you have a dye-test of a direct cotton black, which in its manufacture has involved twenty-one distinct chemical operations, yet it is known in the dyeing trade as a common black. The amount of preliminary and intermediate work which has to be done before a colour can actually be produced from coal-tar is very large: it is the amount of this preliminary work which makes the progress appear so slow to those people who have no conception of the detail work in colour making.

The future of the British coal-tar colour industry is a fascinating subject, about which every man may speculate, but of which no man may speak with certitude. True to our national character, the scientific pessimists are enjoying themselves preaching national disaster unless their own particular nostrums are adopted. I am unmoved by these predictions. I am old enough to remember the British push-cycle trade being told that the American push-cycle would sweep them out of the market: where is the American push-cycle in Great Britain to-day? The same jeremiads were sung about the British motor trade as compared with the French: does not the British motor to-day stand unsurpassed? Of more recent date, the British aeroplane has been denounced as inefficient, but which aeroplane flies over its enemy's lines the more—the British or the German? Therefore, I am unmoved by the prophets of gloom concerning the coal-tar trade colour. At the outbreak of war predictions of dire disaster were prophesied to the textile trade, owing to the shutting off of German colours. Those predictions have been completely falsified, because what do we actually find? We find the shares of the leading colour-consuming companies in this country actually standing at much higher figures than they were before the war: textile shares are one of the features of the Stock Exchanges. I maintain that the British firms can claim a share in that very satisfactory state of affairs, owing to the way in which they have expanded their supplies. The British firms had not only the future for which to provide, but they had also the immediate shortage with which to deal. Naturally steps had to be taken which would not in normal times have been tolerated, but the successful way in which they dealt with that shortage is reflected in the equipment of the British army, and in the fact that the dyeing trade, instead of sinking in disaster, has never been so prosperous.

The war has opened the eyes of the world to the value of the chemist, who now bids fair to be granted that status which should always have been his. The future is with the trained chemist. Research is now being organised on a scale which has never before been attempted in Great Britain, and British Dyes, Ltd., are happy to know that the director of their research department, in the person of Professor W. H. Perkin, possesses a name of the happiest augury in the coal-tar colour industry.

When I think of the army of research chemists employed in the past by the German firms, I am amazed, not at the results which they have produced, but I am amazed that the results were not much greater. The German firms employed mass tactics with their chemists, just as their General Staff employ mass tactics with their soldiers. Why should not the British chemist do quite as well as the German chemist? He is at last being given a chance to fight on equal terms. The future will show the outcome of that fight. Speaking for my colleagues, we enter the fight with full knowledge of its severity, but with great keenness and every confidence.

Cannot the pessimists draw some cheer from the success of the national efforts in the manufacture of high explosives? We never pretended to be a nation skilled in industrial organic chemistry, but look at the splendid results produced in a short time by British chemists in the matter of high explosives under the organising genius and enthusiasm of Lord Moulton.

If the British consumers are honest in their desire not to buy German dyes again, there are already many dyes on the list which they need never buy from Germany again, and this list will grow rapidly in the near future. The

future of the British coal-tar colour industry depends as much on the good-will of the consumer as on the industry itself. Let sympathy and patience be extended to the industry during these early days of expansion—the task in front of the industry is sufficiently heavy to warrant it.

DISCUSSION.

THE CHAIRMAN (Sir William A. Tilden, D.Sc., Sc.D., LL.D., F.R.S., F.C.S., F.I.C.) said they had listened to something which must be a great encouragement not only to the chemist and the manufacturer, but to the public in general. He himself felt much happier for having heard the paper.

DR. M. O. FORSTER, F.R.S., said the point in the paper as to the importance of the contribution to the colour industry which had been made by British firms before the war needed emphasis, because it was very often lost sight of in the discussion of this subject. If a comparison were made of the condition of the British colour industry before the war with that of the colour industry in other countries, excluding Germany, it would be found that, with the single exception of Switzerland, Great Britain was far and away ahead of all others. France had a colour industry before the war, but it was practically an intermediate assembling industry—*i.e.* the large colour factories which existed in France before the war imported intermediates from Germany and simply assembled them. Consequently, with one or two small exceptions, there could not be said to exist in France any indigenous colour industry. In America the case was similar. There were one or two small factories so far as the home supply of intermediates was concerned, but most of the colours in America were made from German-supplied intermediates. In this country it was true we imported large quantities of intermediates, but there was also a substantial intermediate manufacture here, so that in that respect we were ahead of those other countries, except Switzerland. It was the question of the intermediates which, in his opinion, stood at the root of the whole difficulty. We did not make enough of these intermediates in this country, and the whole energies of the colour manufacturers must be bent towards meeting that difficulty. When it was realised that there were something like eighty or one hundred intermediates of greater or less importance, each one of which often involved six, eight, ten, and sometimes as many as twenty separate chemical operations in its production, some idea would be gained of the extraordinary complexity of this industry. There was one matter he would like to call attention to which had always seemed to him to be one of the blots of the colour industry, and it was the ridiculous confusion in the nomenclature of colours. In the November number of the American *Chemical Engineer* there was an extraordinarily interesting report by Mr. T. H. Norton, describing the census of the American consumption of colours, which had been taken before the war. This was deserving of the attention of everybody who was interested in this matter. It took two years to complete this census, owing to the extraordinary reluctance of the consumers to provide the information. Eventually it was compiled from the sheets of the Customs House officers, showing the imports of the various colours at the different ports, and it was discovered that there were more than five thousand different names of colours. The whole range of colours was not more than eight hundred or a thousand, and there was such a waste of time from the variety of nomenclature that some change was necessary in that respect. Many of the names, it would appear, had been introduced simply to confuse competitors. That, up to a certain point, was a perfectly legitimate motive, but it had also been done to exercise a kind of tyranny over the users, so that the user, once caught, should not escape the clutches of the particular dye-maker. Users did not have the technical knowledge to ascertain what were the colours they were actually using, and they simply took them on the label from the people who supplied them. That practice of confusing the issue by all these different names for the same thing should be abolished, and the confusion of taking the same name and adding to it a number of more or less misleading letters, which simply indicated the degrees of dilution, should also be abolished, because it would be quite easy to give the name of the colour and add after it the percentage of actual colour in the particular sample which was being sold. He hoped that Mr. Whittaker would use his influence in this direction.

MR. W. L. OAKDEN asked if there were any dyes or colours which it would be impossible to manufacture in this country for want of materials, and for which we should have to depend upon Germany. Supposing we could manufacture all colours, did Mr. Whittaker think that some restrictive measures could be taken to prevent Germany dumping their colours on this country after the war?

MR. CHARLES BEDFORD, as a member of a family that had been manufacturing natural colours for a hundred years, said he appreciated the competition which British firms had had to meet during the last thirty years from Germany, not only from the fact that chemical science had been developed there to a very large extent, but also because of the greater attention given to higher education and business training generally. He remembered very well, in 1887, he patented a colour in which the colouring matter of fustic was combined with diazobenzene chloride. It was rather interesting at the time as a combination of natural and artificial colouring matter. That had not been in existence three months before he was called upon by a representative of the Badische Anilin Company asking

for a licence to manufacture. He objected, but was told that so much capital would be brought against him that he would have to grant the licence. The Badische Company manufactured the colour under licence for several years until mordant yellow made its appearance, when the demand declined. There was now little doubt that after the war British colour-makers would be able to take their place in the world's markets and supplant German colours.

Mr. W. F. Leeson said that there were probably very few present besides himself who had heard Perkin describe his discovery of coal-tar colours. It had been a matter of deep regret to him to see the trade slip away to Germany, but he now rejoiced that we were likely to re-establish this great British industry.

Mr. J. Wilson expressed the hope that British colour-makers would adopt a more generous attitude to teaching institutions in the future than they had done in the past. A few years ago, in the institution with which he was connected—a London institution—they endeavoured to start instruction in dyeing. Naturally they wanted samples of dyestuffs, but the response received from British makers was singularly discouraging. On the other hand, German firms sent some 700 or 800 samples, and consequently the students always had before them German dyestuffs. He was glad to say that, so far as Mr. Whittaker's firm was concerned, that attitude was now completely altered; but he hoped British firms generally would be more generous in the future for their own sake, and certainly for the sake of the development of technical science in this country.

The Chairman said Mr. Wilson's experience did not accord with his own, for thirty years ago he had found British firms very willing to help teaching institutions.

Mr. James Swinburne, F.R.S., said it did not follow in the least that because before the war we did not make certain things we were incapable of making them. We made things which we exported, and we must have something in exchange. The fact that on the whole it had paid us best to take dyes as one portion of our exchange did not in the least show that, if necessary, we were not just as able to make dyes as the Germans. We had had to make dyes during the war, and British firms had gone ahead tremendously under every conceivable kind of disadvantage, but the real question was what would be the position after the war of a concern like British Dyes, Ltd.? If we had only dyes to think of in connection with our foreign trade, we could, no doubt, by some fiscal means safeguard the industry, but other things had to be exported; and, taking the larger view, the question was whether British dyes would be able to hold their own against German cheapness after the war. As far as the German chemist was concerned, he was a plodding man, with no sense of proportion and no originality. The British chemist, on the other hand, went at things in a properly balanced kind of way, and he had imagination and new ideas. Consequently, instead of taking up the manufacture of existing colours, as the dye-makers in England were doing now, we should soon see the British chemist inventing better dyes which would replace the German dyes. If we could only get over the difficulties which must occur when the war was over, there was a great future not only for the British chemist, but for the chemical engineer.

Mr. R. E. Oldroyd, speaking as a user, expressed appreciation of the efforts made on their behalf by British Dyes, Ltd. With regard to the large number of names mentioned by Dr. Forster, he must confess to being one of the culprits, and Mr. Whittaker had helped him to put a number of new names on the market. A certain number of colours were produced for his special use, and these were all given new and distinctive names, and that was the reason for so many different markings on the various colours. A previous speaker seemed to be afraid that our manufacturers of colours could not compete in the future, and raised the usual cry that we would have to be protected. He did not think so. If we looked at the trade carefully, we should see that it had all the protection it needed. There was indeed one protection which the dye-maker could rely upon, and that was the support of the English user. He was chairman of a guild of users, and the majority of the members had agreed in future to support British dyes whenever it was possible to get them. In the past it had not always been possible to get them. The other protection the makers now had was the guarantee of the supply of the chief chemicals with which to make their dyes. The Government department concerned in explosives had now made arrangements for chemicals, and the large number of acid plants erected for explosives would be available for the dyeing industry after the war. Moreover, the capital charges on these plants would have been largely written off during the war, and makers should be able to look forward to as cheap chemicals as were obtained by their German competitors. Further than that, the German maker would not be in the same position after the war as he was before. Although the Germans had not the world's supply of bromine, yet they had a monopoly, but there were other chemicals which would balance that. After the war we should be able to keep a hold on the heavier chemicals, which the Germans got to a very great extent from our large makers, and so prevent any monopoly on that side of the industry. At present the dye-maker was suffering because the plants supplying the chemicals for high explosives were the same as those from which dye chemicals came, but after the war those plants

would be available, and then the industry would be much more secure than had hitherto been the case.

Mr. Walter F. Reid called attention to a point not mentioned in the paper, viz., the very large incomes produced to German manufacturers of dyes from synthetic remedies. They were synthetic, undoubtedly, but whether they were remedies was quite another question. At any rate, they had made the civilised world believe they are remedies, but the mortality from taking some of these drugs was growing very rapidly. Nevertheless, their manufacture was a source of great income, and it was a subject we should not lose sight of altogether. One thing that ran throughout the paper was the rather unnecessary apologetic view taken of what the British dye industry had done. He came into contact with a very large number of technical chemists, and he had not heard this disparaging language used very frequently. Whenever it had been used it was by people who had had no experience of the industry. Those who did know had nothing but praise for British chemists, who, without previous experience, had worked out most difficult processes, sometimes with only a patent specification to guide them that was made to mislead in the first instance. One piece of personal experience, however, he had. The dyes used on the uniforms of volunteers were by no means fast, as a glance at a regiment of volunteers showed. He hoped British makers, when they did put these dyes on the market, would give as good as their competitors did previously. As to the number of colours, it was a general supposition that the ladies required a certain number of new shades each year, but he did not think they really wanted them at all. They only bought them because they saw them in the shops and they looked pretty. If the dyers and those who used dyes would agree to limit the number of dyes to, say, one thousand, that would be the best measure of protection against foreign dyes they could possibly have, because a German traveller coming here with patterns of beautiful dyes would not be able to persuade buyers to use them.

Mr. Whittaker, replying first on the question of the number of dye names, said he could not hold out much hope that it would ever be remedied. In most cases they were colours made by many firms, and unless special names were used the firm for whom the order was intended might not get it. For instance, if B. H. black were ordered it would be known that it was to be supplied by Read Holliday & Co.

Dr. Forster said he thought it affected the question of the multiplicity of names. Mr. Whittaker had said that there might be a number of names for a perfectly definite thing which everybody was making. It was not as if it were a proprietary article of which only one firm had the secrets.

Mr. Whittaker, continuing his reply, said the only product for which we would have to depend upon Germany was bromine. At present there were a number of dyes we could not manufacture, but not from want of materials. That would be remedied in time. As regards the attitude of British firms to teaching institutions, the fact that British Dyes, Ltd., had made a grant of £5,000 towards the coal-tar colour department of the Huddersfield Technical College was proof that whatever their faults in the past, they had mended their ways now. Concerning the exchange of products, Mr. Swinburne's argument was true; but it was rather unfortunate when the exchange product was a pivot industry on which the whole of the textile industry depended. As regards the fastness of dyes, he maintained that those supplied for khaki uniforms were equal to anything from Germany.

A hearty vote of thanks was accorded the author at the conclusion of the discussion.

ARTS AND CRAFTS.

Mr. Nelson Dawson's War Memorials.—Mr. Nelson Dawson's little exhibition of Records and Memorials at the Fine Art Society's galleries is interesting from two very different points of view. To begin with, the exhibits are the work of an artist who thoroughly understands his material and whose work has always a certain distinction. But the show in Bond Street has another and a rather more unexpected attraction. In it Mr. Dawson has tried not so much to show what can be done in the way of large and elaborate memorials, as to demonstrate that the smallest wall tablet, so long as it is well designed and has a character of its own, may be a really worthy memorial. This is a point which has had far too little attention paid to it. People in days past have had no appreciation of the value of wall space in our cathedrals and parish churches, and it is high time that the question of the size of memorial slabs and the like received serious attention. It is only men and women of real and outstanding distinction who ought to be commemorated in public places by large memorials. Mr. Nelson Dawson's idea of making a tablet some 12 in. or 18 in. high, either wrought entirely in metal (with or without some enamel on it) or with the metal ornamentation mounted on an appropriate wooden slab, is one which has a great deal to commend it. His selection of heraldic devices as his principal *motifs* has, further, led to very happy results. His whole handling of his subject suggests inevitably the question of the wider treatment of commemorative tablets in schools, colleges and other institutions in which some record is wanted of those who have served and fallen in the war. A mere list of names is not always

sufficient. It is a rather bald acknowledgment after all, except in the very rare cases where the lettering itself is a work of art. A number of small memorial tablets dotted casually about a wall have that spotty and altogether unsatisfactory effect with which we are all so familiar in churches and other places. Mr. Dawson's small tablets, treated as they all are in much the same manner, dependent on shields and coats of arms for their main interest, carry us almost before we are aware to the thought of a whole series of such designs, all of the same type and yet differing from each other as the work of any true artist needs must, serving to decorate a hall or chapel, either in the form of a kind of dado line carried right round, or as a carefully planned and considered group at the end of the room or at some central point.

The "Englishwoman" Exhibition of Arts and Handicrafts.—Exhibitions of Arts and Crafts devoted entirely to women's work are not, as a rule, very satisfying affairs from the point of view of art. There is, for the most part, an air of amateurishness about them which tends to make the scoffer rate women's achievements far below their real standard. The *Englishwoman* Exhibition of Arts and Handicrafts, held this year for the second time at the Central Hall, Westminster, cannot be said to have been altogether free from the defects which characterise other undertakings of a somewhat similar type; but it was, on the whole, a very interesting show. Though rather weak in some directions, in others it proved itself very strong indeed. This is the more noteworthy as so much of the work on view at Burlington House at the same time was executed by women that it would not have been surprising had the level at another exhibition held contemporaneously fallen below the normal standard. It is true that some of the more important branches of women's art work were not very adequately represented at the Central Hall: the metalwork, for instance, was unimportant, and the jewellery, compared with the best work at the Arts and Crafts, was very far behind. Moreover, there were a certain (not a very large) number of stalls devoted to what can only be called the fripperies and eccentricities of artistic craftwork. On the other hand, the exhibits of weaving, lace-making, embroidery, toy-making, etc., if not very remarkable individually, revealed collectively an amount of honest, persevering and intelligent work by a number of women which is full of hope and promise for the future. The colour of much of the weaving was particularly good, and some of the industries (notably Shottery) are weaving patterns in colour at the ends of cloths and towels which suggest old Italian needlework. The embroidery was often skilfully arranged to be suitable for dress decoration; for instance, the overalls of various shapes and sizes, with just enough simple stitchery to give them individuality, were a very happy idea. The Celtic designs, again, carried out in tasteful colours by the Dun Emer Guild, were as attractive as ever. Amongst the toys, the most successful were perhaps the wooden animals, farms, Noah's arks and the like, which made one wonder how we had ever put up with the atrocities which were the invariable rule before the war. There was some good illumination and also some parchments decorated more or less in Italian fashion which were less satisfactory. On the whole, the works shown reached a really high level, and the exhibition left one with the impression that women hand-workers are advancing both in technique and in taste.

OBITUARY.

COLONEL THOMAS EDGAR JOBLING.—Colonel T. E. Jobling, of Bebside Hall, near Blyth, died, after a brief illness, on October 7th.

Colonel Jobling was the managing owner of the Choppington and Bebside Coal Company, and the Vice-President of the Northumberland Coalowners' Association. He was an Alderman of the County Council, and for many years was Chairman of the Elementary sub-committee of the Education Authority, but resigned the position about twelve months ago. He was elected a member on the formation of the County Council, and took a considerable part in the administrative work of that body. He was Chairman of the old Cowpen Local Board, and Chairman of the Cowpen School Board, holding that position until the dissolution of those authorities. He had an almost life-long connection with the Volunteer movement, having joined the Tynemouth Artillery Volunteers when quite a young man. He identified himself with the voluntary recruiting campaign after the outbreak of war, and latterly represented the military authorities at the local tribunal. He was chairman of the Blyth bench of magistrates.

He was elected a life member of the Royal Society of Arts in 1885.

GENERAL NOTES.

TECHNOLOGICAL EXAMINATIONS.—The report on the examinations for the current year of the City and Guilds Institute has just been published. Like all other examining bodies, the Institute has suffered seriously in the numbers of its candidates during the past two years. In 1913-14 there were altogether 23,119 who came up for examination. Last year this number dropped to 15,623, and this year to 8,508. There was also a falling-off in the number of centres: this year there were 316, last year 419, and the year before 467. The record year seems to have been 1910, when 24,508 were

examined at 418 centres. The number of subjects of examination has now reached 79, a considerable development of the 14 which the Society handed over to the Institute in the year 1879.

HARVEST IN WAR ZONE IN FRANCE.—The harvest in the war zone in France, this year, appears to have been a fairly good one, judging from a report made by the military authorities. The production of wheat in the three Departments of the Oise, Somme, and Nord were slightly below the average, whilst that of the Pas-de-Calais, notwithstanding the dearth of hands and difficulties of transport, showed better results than in 1915. The oat crops showed a decided improvement. The prospects of the beet crops, both for sugar-making and for distilling, promise well, and a production above the average may be predicted.

ECONOMY IN BREAD-MAKING.—With the price of wheat still rising, it is interesting to learn that a new process of bread-making, direct from the corn, without the preliminary conversion into flour, is in operation in the municipal bakery at Bergamo (Italy). The wheat, which must be first thoroughly cleaned, is then soaked in hot water for twenty-four hours, more or less, according to its degree of hardness. During this time it commences to germinate and undergo a complete transformation. This pasty mass is next kneaded into dough, yeast is then added, and the whole worked up to the proper consistency, allowed to rise, then formed into loaves, and baked in the oven in the usual manner. Bread made in this way is said to be quite as palatable and far more nourishing than the ordinary wholemeal article, containing as it does all the constituent parts of the wheat. It is claimed, moreover, that a saving of 25 per cent. in the cost of bread-making is effected by this direct process, and at the same time a larger yield from the corn is obtained.

CHEMICAL FILTER PAPER.—In the course of an article on this subject in a recent issue of the *Analyst*, Mr. E. J. Bevan and Mr. W. Bacon state that it is estimated that, prior to the war, 500,000 to 600,000 lb. of filter paper of all grades were imported into this country; at the present time only four English paper-makers are producing filter paper, but excellent qualities of paper are now on the market. For most filtering purposes a paper should possess the character of "softness," and the technical term for this is "bulk," a term defining the relation of the volume of the paper to the volume of the fibre; generally, for a moderately rapid filter paper the bulk should be about 3·5 (fibre = 1). Pinholes sometimes occur in papers of this class and are due to faulty manipulation of the beaten stuff at the mill. Cotton cellulose is preferable to linen (flax) cellulose in the manufacture of high-grade filter papers owing to its low hydrating power and to the fact that it imparts more bulk to a paper. It is difficult to get new waste material for this manufacture, and the source of many of the chemical impurities in the finished paper may be traced back to the raw material. The lime present in filter paper is chiefly derived from the water used in the manufacture; chemical bleaching of the material also contributes to this impurity. Iron and copper are frequently present and sometimes alumina and silica, due to loading of the material with kaolin. Starch and oil are the chief organic impurities in filter paper; both are derived from the raw material, and are for the greater part removed by the alkali treatment and washing.

COTTON MANUFACTURE IN CHINA.—According to the report for 1915 of the Commissioner of Customs at Tientsin, the difficulty experienced in obtaining adequate supplies of cotton piece-goods from abroad has resulted in a considerable stimulus to the manufacture of these goods by local Chinese factories. Factories equipped with modern machinery were erected in several localities under Chinese management and using Chinese labour, foreign experts being engaged to teach the best methods of manufacture and how to make the best use of the machinery. The products of these factories correspond in weight and design to the imported goods, and compete profitably in the open market with similar goods manufactured abroad, the tendency among buyers being apparently in favour of Chinese-made goods in preference to the cheap varieties imported from Japan, or the higher and more expensive grades coming from Europe and America. A group of Chinese merchants has also placed orders in America for the latest spinning machinery, to be used in two new mills for the making of cotton yarn. If these should prove a success, there is no doubt that similar plants will be erected in other parts of North China.

KOREA.—An American, who has recently visited Japan and Korea, sends in a private letter some interesting impressions of Korea, and the progress which the Japanese have made in developing that country. He says: "Japan needs to populate Korea. I spent some weeks there, meeting all sorts of people—Koreans, Japs, British, and Americans. There is only one thing to be said: they are making Korea into a country, with new roads, good hotels, savings banks, electric railways, schools, churches, etc. For the first time Koreans dare to accumulate property, dare to send children to school. The Jap teachers told me the Koreans learned faster than the Japs, evidently having having a real thirst for knowledge. In some of the classes there were pupils of thirty or thirty-five studying and reciting with children

of nine or ten. I visited many schools, some for girls, others for men and boys. It was really an inspiring sight—all these mixed ages working for their education. Imagine this: the best hotel I ever was in, outside of one of the largest cities, was in Seoul. It was built by the Government. Its architecture is excellent. The building materials, white marble, tiles, curtains, etc. (except the chairs, carpets, and window shades), were all Korean. The menu included anything one can get in New York except oysters. Sole, real sole, every day! Drinks! Segars! Certainly, all kinds. The best Havanas at a quarter the price paid in London."

SOCIETY OF ARTS MICROSCOPES.—A correspondent of the *Westminster Gazette* recently drew attention to the large number of microscopes of the Society of Arts pattern which were being offered for sale, second-hand, in a shop on Ludgate Hill. The origin of these instruments is interesting. In 1854 the Society offered two medals, one for a simple and one for a compound microscope, to be supplied at the price of 10*s.* 6*d.* and £3 3*s.* respectively. It was said that at such prices nothing of any practical use could be provided, but Messrs. Field, of Birmingham, produced two excellent instruments at the stipulated prices, and the prizes were awarded to them. The smaller instrument, which is now very familiar, appears to have been then quite novel in construction and design; it was well suited for the examination of botanical and other natural history specimens, and large numbers of it were sold. The larger compound microscope was a thoroughly serviceable instrument, and certainly nothing like it had ever been produced at the price. Public appreciation of it was shown by the fact that by the end of 1861, 1,800 instruments had been sold.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

DECEMBER 13.—H. WILSON FOX, "The Development of Imperial Resources." The RIGHT HON. THE EARL OF SELBORNE, K.G., G.C.M.G., D.C.L., LL.D., will preside.

DECEMBER 20 (at 4 p.m.).—A. C. BENSON C.V.O., Master of Magdalene College, Cambridge, "Classical and Scientific Education." The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

JANUARY 24.—W. A. M. GOODE, Hon. Secretary, National Committee for Relief in Belgium "Relief Work in Belgium."

JANUARY 31.—MISS ELLA C. SYKES, "The Work of the Y.M.C.A. in France."

FEBRUARY 7.—ROBERT FORTESCUE FOX, M.D. "The Future of British Spas."

FEBRUARY 14.—LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

DECEMBER 14.—JOHN AITON TODD, B.L., Professor of Economics, University College Nottingham, "The World's Cotton Supply and India's Share in it." The RIGHT HON. LORD EMMOTT, P.C., G.C.M.G., will preside.

Dates to be hereafter announced:—

JAMES HARRIS VICKERY, LL.B., "German Business Methods."

CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

OCTAVIUS C. BEALE, "British Arts and Crafts after the War."

COLONEL SIR THOMAS H. HOLDICH, R.E. K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel."

SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

January 18, February 15, March 15, April 19 May 17.

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

January 30, February 27, March 27, May 1

Howard Lectures.

Monday afternoons, at 5 p.m.:—

John S. S. Brame, Professor of Chemistry, Royal Naval College, Greenwich, "Coal and its Economic Utilisation." Three Lectures.

Lecture III.—December 11.—Directions in which economy may be realised—Economy in production—The utilisation of small and low-grade coal—Improvements by suitable preparation for market—Economy in use—By-product recovery—Economies possible from centralised systems of power generation: from extended use of carbonised coal, including gas—Low temperature carbonising schemes.

William Ripper, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

Cantor Lectures.

Monday afternoons, at 4.30 p.m.:—

Professor A. Beresford Pite, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

Aldred Lectures.

Monday afternoons, at 4.30 p.m.:—

Lawrence Weaver, F.S.A., "Memorials and Monuments." Three Lectures.

March 6, 13, 20.

Juvenile Lectures.

Wednesday afternoons, at 3 p.m.:—

Alan A. Campbell Swinton, F.R.S., "Electricity and its Applications." Two Lectures.

January 3, 10.

MEETINGS FOR THE ENSUING WEEK.

Monday, December 11...Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. (Howard Lecture.) Professor J. S. S. Brame, "Coal and its Economic Utilisation." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. W. St. Clair Tisdale, "The Influence of Christianity upon other Religious Systems." (Gunning Prize Essay.)

Engineers, Society of, at the Geological Society, Burlington House, W., 3 p.m. 1. Professor W. G. Fearnsides, "The Sources of the Minerals required by the Iron and Steel Industries of the United Kingdom." 2. Professor C. G. Cullis, "The Mineral Resources of the British Empire as regards the Production of Non-Ferrous Industrial Metals."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Professor K. J. J. Mackenzie, "Suggestions for the Improvement of Cattle-Breeding in Great Britain."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Presidential Address by Mr. F. W. Lanchester, "Industrial Engineering: Present Position and Post-War Outlook."

Tuesday, December 12...Cold Storage and Ice Association, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Mr. J. W. Anderson, "Education and Research in the Refrigerating Industry."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Dr. A. Cowley, "Professor Hrozny's Views on the Hittite Question."

Colonial Institute, Hotel Cecil, Strand, W.C., 8.30 p.m. Sir Walter Raleigh, "The Ordeal of Empire."

Wednesday, December 13...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Mr. H. Wilson Fox, "The Development of Imperial Resources."

Automobile Engineers, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. F. W. Lanchester, "Worm Gear and Worm Gear Mounting."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Dr. Pinches, "Some Texts of the Relph Collection—with Notes on Babylonian Chronology and Genesis xiv."

Japan Society, 20, Hanover-square, W., 3.30 p.m., Mr. R. P. Porter, "My Visits to Japan (1896-1916)."

Thursday, December 14...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Professor J. A. Todd, "The World's Cotton Supply and India's Share in it."

Geographical Society, Kensington-gore, W., 5 p.m. Discussion, to be opened by the Secretary, on "British and Metric Measures in Geographical Work."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W. 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Miss I. McClatchie, "Observations on the Root System of *Impatiens Roylei*, Walp." 2. Dr. A. S. Woodward, "On the Teeth of some Palæozoic Sharks." 3. Miss A. J. Davey and Miss M. Gibson, "Sex Distribution in *Myrica Gale*, Linn."

British Academy, in the Theatre, Burlington-gardens, W., 5.15 p.m. (Schweich Lectures.) Professor L. W. King, "Legends of Egypt and Babylon in Relation to Hebrew Tradition." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Ten-minute lecturettes by Members.

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. L. C. Martin, "The Refractometry and Identification of Glass Specimens—especially Lenses." 2. Dr. R. S. Clay, "A Workshop Method of Determining the Refractive Index of a Piece of Glass having one flat Surface."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. R. W. Weightman, "Colonial Telegraphs and Telephones."

Chadwick Public Lecture, at the Surveyor's Institution, Great George-street, S.W., 5.15 p.m. Mr. P. Waterhouse, "Architecture in Relation to Health and Welfare." (Lecture III.)

Friday, December 15...Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, Westminster, S.W., 6 p.m. Mr. R. E. Phillips, "Variable-Speed Gears for Motor Road Vehicles."

Illuminating Engineering Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Address by Mr. L. Gaster on "War Economies in Lighting."

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—December 8, 1916.

Journal of the Royal Society of Arts.

No. 3,343. VOL. LXV.

FRIDAY, DECEMBER 15, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, DECEMBER 20th, at 4 p.m. (Ordinary Meeting.) A. C. BENSON, C.V.O., Master of Magdalene College, Cambridge, "Classical and Scientific Education." The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

[Fellows are requested to note that the hour of the meeting is 4 p.m.]

Further particulars of the Society's meetings will be found at the end of this number.

HOWARD LECTURE.

On Monday afternoon, December 11th, Mr. JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, delivered the third and last lecture of his course on "Coal and its Economic Utilisation."

On the motion of the CHAIRMAN a vote of thanks was accorded to Professor Brame for his interesting course.

The lectures will be published in the *Journal* during the Christmas recess.

COLONIAL SECTION COMMITTEE.

A meeting of the Committee of the Colonial Section was held on Tuesday afternoon, the 12th inst. Present:—

Lord Blyth (Chairman of the Committee), Byron Brenan, C.M.G., Richard Ernest Brounger, Hon. Sir John A. Cockburn, K.C.M.G., Edward R. Davson, Major Edward Humphrey Manisty Leggett, R.E., D.S.O., George Wilson, C.B., with Sir Henry Trueman Wood, Secretary of the Society, and S. Digby, C.I.E., Secretary of the Section.

JUVENILE LECTURES.

A Member of the Council, Mr. Alan A. Campbell Swinton, F.R.S., has kindly undertaken to deliver the Juvenile Lectures this year on "Electricity and its Applications." The lectures will be delivered on Wednesdays, January 3rd and 10th, at 3 p.m. They will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 13th, 1916; The RIGHT HON. THE EARL OF SELBORNE, K.G., P.C., G.C.M.G., D.C.L., late High Commissioner for South Africa and Governor of the Transvaal and the Orange River Colony, in the chair.

The following candidates were balloted for and duly elected Fellows of the Society:—

Collett, Leopold George, Merle House, Evesham.

Deas, Edmund Percy, 52, Larkspur-terrace, Newcastle-upon-Tyne.

Notley, Miss Mabel Emily, Larksfield, Englefield Green, Surrey.

Pegler, Alfred, 81, Palace-road, Streatham Hill, London, S.W.

Souza, Francis Xavier Da Silva e, 17, Nakayamate dori, Nichome, Kobe, Japan.

The paper read was—

THE DEVELOPMENT OF IMPERIAL RESOURCES.

By H. Wilson Fox.

Some of you may have read the articles which I recently contributed to the *Times* upon the subject with which this paper deals. Those articles pointed out that at the end of the war we must necessarily look forward to an Empire debt, and an annual national expenditure of such dimensions that, unless some new method of dealing with national finance can be devised, we shall be faced with a burden of taxation which may become a very serious menace to our national well-being and progress. I urged that before we resigned ourselves to such a prospect we should consider whether there was any practicable alternative, and suggested that the solution of our financial difficulties lay in the systematic development by the State for the State of some of the at present undeveloped resources of our vast Empire.

I propose this afternoon to enter somewhat more fully than was possible within the limits of those articles into some of the varied aspects of this suggestion, and with the special object of viewing it primarily from an economic standpoint.

I shall refer briefly in the first instance to some of the criticisms which very naturally have been made upon it. The first which I shall mention is rather political than economic. People say, "Oh, this is rank Socialism; we cannot possibly agree to proposals of this nature; we do not know where they will lead us. This is the thin end of the wedge!" Or, as a friend of mine has wittily expressed it, "They will say, 'You want to make me a Socialist. I have only just begun to think Imperially, and now you want me to think Socialistically.'"

The answer to this criticism appears to me to be that we are Socialists all the time. It is a mere question of degree, and if, by being slightly more Socialistic than we are at present, we can all be a great deal better off I for one am quite prepared to be a Socialist. But I think that the real reason why so many people are frightened at the bogey of Socialism is that, like so many other words which have been flung into the melting-pot of political strife, it has become besmirched, and meanings have been attached to it which are quite foreign to its proper connotation. Moderate people have been led to regard a Socialist as a man who wants to rob someone else—that is, a man who ought to be watched all the time and handed over to a policeman on the first opportunity. Let me assure you, right here as an American would say, that that is not the sort of Socialism for which I have any sympathy. On the contrary, I want the State to leave money in people's pockets, instead of taking it out of them, and to create new wealth for itself—in the general interests of all of us—by developing, or helping to develop, a fraction of the vast undeveloped resources of the greatest Empire which the world has ever seen, and I believe ever will see. We are certainly Socialistic in our expenditure; let us try to be Socialistic in the right sense of the word in creating our revenue.

But again it is said, "Ah, but in doing what you propose are you not depriving individuals of their legitimate opportunities? Are you not running the risk of undermining the very bases of our national greatness, and of destroying that individual initiative and application to which we have mainly owed our past prosperity?" I think that there is a great deal more in this criticism than there is in the first one, and I freely admit that if the effect of my proposals must necessarily be to interfere gravely with the work and opportunities of individuals I should certainly be opposed to them myself. But I believe that activity begets activity, and that well-ordered State action will, so far from diminishing the opportunities of individuals, very greatly enlarge them. Who will dare to place a limit upon the opportunities offered by our Empire? We have hardly as yet touched the fringe of the possibilities. Increased production, whether by the State or by individuals, will, if wisely planned, necessarily increase both population and consumption by giving to each and all better facilities for satisfying their desires; while education, research and organisation are daily giving rise to a better return for effort. In other words, as time goes on, we ought to be able to live better while working less. There is not the slightest necessity, so far as I can see, why State action such as I propose should interfere detrimentally either with capitalist or with labourer, except in cases where any fair-minded man would think it right and just in the general

interests of the community that it should do so. As to this it may be said, "Yes, that seems right on the face of it, but it is too general. We should like to know more definitely what limitations it is proposed to place on State action?" The answer to this question is important, and can, perhaps, be stated best as a series of propositions:—

1. The State should not compete with private enterprise except where such private enterprise tends to become a private monopoly and to "hold up" the consumer.

2. Its intervention must always be on a sound economic basis.

3. Public industrial enterprise should as far as possible benefit capital as well as labour.

4. It should be clearly shown to be in the national interest.

5. It should be shaped and directed to the exploitation of natural monopolies, natural wealth, industries vital to public safety, key industries, seasonal trades, and industries affecting public health.

This statement of the proper limits of State action is not my own, and it covers somewhat wider ground than that with which I am concerned this evening. I rejoice to tell you that it is taken from an article recently contributed by Mr. Victor Fisher, one of the ablest members of the Labour Party, to the *British Citizen and Empire Worker*, and I find in it a message of great hope and encouragement. If that is the spirit in which these great problems are being approached by prominent members of what will sooner or later become the most powerful section of this community, we need have no fear for the future of our Empire. To solve our problems we must approach them in a non-partisan temper, in a spirit of broad-minded tolerance and unhampered by preconceived prejudices; and, above all, we must escape from the poisonous atmosphere spread by old political shibboleths which even this great war has not as yet finally destroyed. We must look at things as they are and pay no heed to what they may be called, and we must welcome clear thinking and patriotic ideas wherever we may find them.

The next criticism which I shall mention is of the nature, "Physician heal thyself." I have heard it said, "How is it, if State development is practicable, that the British South Africa Company cannot show better results after all these years?" This is not an occasion when I can enlarge upon the work of that great Company; but, in reply to this criticism, I will point out certain facts in regard to Rhodesia which furnish, I think, a sufficient answer. It must not be forgotten that when Rhodesia was first occupied in 1890 it was a barbarous and wholly inland territory, separated from the nearest centres of civilisation of South Africa by many hundreds of miles of sandy desert, and from the sea at Beira by over two hundred miles of broken mountainous country, of tropical forest and poisonous swamps. Until railways had been carried to its border in 1898 development in any commercial sense was impracticable, and the more so because many hundreds of miles of line had still to be built to link up what are now the main producing centres with each other and the sea. The South African war broke out, you will remember, in 1899, and it was followed by a period of great financial difficulty. I have no hesitation, therefore, in asserting that the real development of Rhodesia only began less than fifteen years ago, and in claiming that a country which, in the circumstances of Rhodesia, has already developed an external trade of about £8,000,000 per annum, has every reason to be proud of its present condition and to be sanguine as to its future. A Board of Imperial Development is not likely to select for its initial work portions of the Empire which present similar difficulties. It will have a wide choice of opportunities, and will naturally deal with them in the order of their respective attractiveness. Any comparison with the work of the British South Africa Company is consequently liable to be completely misleading.

I have reserved to the last the criticism which is the most difficult of all to answer satisfactorily. It is concerned with the question of State management. People say: "The State never could and never can manage any commercial enterprise successfully. Civil servants are notoriously even as children in business matters, and, besides, any organisation such as you propose is bound to fail, because it must inevitably become a hotbed of political jobbery." The only answer to be made to this criticism is that it ought not to be so. There are plenty of men available in this country who have given their proofs in the management of great business undertakings. Our fellow-countrymen are not inferior in their powers of organisation to the organisers of any country in the world, not excepting Germany; and, having the material, it seems to me that it would be a most humiliating confession of national incapacity to assume that proper use cannot be made of it. Moreover, in this special

direction the war has been a great educator. The State is to-day by far the greatest of our industrial employers in respect of the operations of the Munitions Department alone, and many of its factories are equal if not superior in lay-out and equipment to any others in the world. In many directions action which might have been impracticable, or at any rate very difficult, before the war has become to-day comparatively easy; and I, for one, believe that a great extension of State activities in the sphere of the production, distribution and exchange of wealth could now be successfully organised with great benefit to the Empire. At any rate I am certain that efforts in this direction ought to be made, and I am confirmed in this view by consideration of our national financial position.

I do not propose to weary you this afternoon with a mass of figures, partly because all such figures, and especially estimates for the future, can be only, to say the least, approximate. I think, however, that it may be useful to restate some of the considerations which lead to the conclusion that some new system for raising a large proportion of our State revenue is urgently needed. It appears to be more or less agreed by statisticians that our national income before the war was about £2,400,000,000, and that the accumulated wealth of the United Kingdom was about £16,000,000,000, and of the Empire about £30,000,000,000. Partly owing to the recent rise in prices these figures have now changed considerably; but, as I am concerned rather with the wealth itself than with the valuation of it, the pre-war figures will best serve my present purpose. The pre-war savings of the nation per annum are estimated at something less than one-fifth of the national income, and, it must be remembered that out of this fund of from £400,000,000 to £500,000,000 per annum the nation has relied for the improvement of its machinery of production. It is not, therefore, to this surplus income that the State can primarily look for the supply of the greater part of its new heavy requirements. To cease to maintain and improve our machinery of production would spell national danger of the gravest character. It must also be remembered that our requirements on account of plant will be very considerable in the first years of peace, and are never likely to return to pre-war figures; because, if production is, as we all hope, to be increased we must spend more money on the purchase, maintenance and improvement of power and labour-saving plant. The demands for this purpose upon our national surplus income will consequently be increased.

Given an adequate supply of capital, and a fresh start in the relations between capital and labour, it is possible, and even probable, that the income from our home industries may increase sufficiently rapidly to make up, say within ten years, for the diminution of our income caused by the sale of our foreign investments, and possibly to furnish the further sums needed for the replacement and improvement of our national plant. But I greatly doubt if it will also supply within the same period a further large margin out of which the new demands of the tax-gatherer can be completely met. To provide the balance the alternatives, therefore, are either to induce greater national economy, or to find some other source of State income, or both. The distribution of national income makes it very doubtful whether under existing social and political conditions it is possible or desirable to impose greatly increased taxation upon that portion of the national income which is received by persons having an income of less than £700 per annum. That portion probably represented not less than £1,850,000,000 out of a national income of £2,400,000,000, and by far the greater share of it was received by persons in receipt of incomes of less than £150 per annum. On the other hand, if the greater portion of the burden were cast upon the recipients of the remaining £550,000,000 the consequences, as I have indicated, would probably be highly injurious to future production.

It is necessary to consider these matters seriously, because the future additional requirements of the State are likely to represent a high proportion of our former margin of saving. In my recent articles I estimated tentatively the post-war national expenditure including Sinking Fund at £460,000,000 per annum, being an increase of £261,757,000 per annum on the pre-war figures. To-day, I consider that an increase of at least £300,000,000 will probably be nearer the mark, bringing our national expenditure to upwards of £500,000,000 per annum. If the greater part of this additional £300,000,000 cannot, as I suggest, be taken from people with large incomes without national danger, and if we are forced to rely upon taxation alone to meet State necessities, then the burden must fall upon the poorer classes of the community. Such a result would certainly give rise to widespread suffering, and the more so because satisfactory methods of taxation have still to be devised.

With regard to our accumulated wealth, Sir George Paish* has pointed out, "That it is for the most part merely the land on which we live, manufacture, trade and grow our crops, our factories, railways, machinery, shops, houses, furniture, etc., and that its value consists in its use for purposes of production and of income. . . . Thus our accumulated wealth for the greater part consists of the machinery of production, using the term in its broadest sense, of use for the purpose of production, but unavailable for any other purpose than production."

I quote this statement because it suggests the reason why we should now look with hope and expectation to our overseas estates to help us to make good the heavy losses of material wealth which the war has caused us, and to assist us to meet our national liabilities. The reason broadly is this: We have in many of our Possessions the machinery of production already partially assembled; but, the machinery being still incomplete, it cannot as yet be described as accumulated wealth. It is potential wealth, and more remains to be done before it can be converted to our immediate use. We have the fertile lands there, and the labour, and with a modicum of capital—and above all, by the aid of effective organisation—the whole machinery of production can be assembled and set to work. Out of an income of, say, £2,400,000,000 per annum, with a margin of saving for purposes other than the necessary extension of our machinery of production of considerably less under pre-war conditions than £500,000,000 per annum, it would not be easy to provide for the extinction of debts of from £4,000,000,000 to £5,000,000,000 with an interest charge of from £200,000,000 to £300,000,000 per annum. On the other hand, to increase the accumulated wealth of the Empire, by, say, 20 per cent. in a reasonable period, from, say, £30,000,000,000 to £36,000,000,000, need not necessarily be a difficult task, bearing in mind that, in the United Kingdom alone, our accumulated wealth is estimated by statisticians to have increased by about £3,000,000,000 in the ten years immediately preceding the war. It should, however, be noted that, as Sir George Paish has pointed out, accumulated wealth does not necessarily mean consumable wealth, to which alone we can look for the service or satisfaction of our national debts. Consumable wealth, which for national purposes may be roughly defined as wealth which can be converted into cash, may, however, exist in many different forms, and in particular may include land for which purchasers can be found.

There is no doubt that many of the undeveloped resources of the Empire can be developed profitably. The first point to be decided in principle is whether the State should in regard to some of them take an active part in their development; or whether in all cases it prefers to leave their development to individuals, assuming itself the position of an agricultural or mineral landlord. In the latter case its overseas revenues will continue to be derived almost entirely from taxation, the sale of unimproved land, or mineral royalties. We are, however, confronted with an unprecedented financial position, and we must decide whether we are satisfied with our existing methods. At any rate it cannot be wrong to appoint a competent expert board to consider these questions. The means which can be employed most advantageously to develop particular forms of wealth may be different. In one case it might be clearly good policy for the State to act directly on its own account; in another through the instrumentality of a corporation in which it takes an active interest and participation; in a third it may be best to leave the whole business to individuals.

There are many ways in which, if it decides to do so, the State can take a direct share in production and the operations consequent upon it. It may, for instance, as an owner of land, develop and cultivate the land itself, and not merely sell or lease it to others who will engage as individuals in the business of mineral or agricultural production. It is to this form of State activity that my present proposals mainly relate, though I am equally in favour of direct State activity in connection with industrial or trading business, provided it can be shown that action in these directions can be taken on lines which will, so far as can be foreseen, be sufficiently remunerative, and which will not be likely to have a discouraging effect upon industrial enterprise generally.

I may point out that the various forms of activity to which I have referred cannot be kept entirely distinct. It is again all a question of degree. A farmer when he brings a crop of corn to maturity is a producer from land, when he thrashes it he becomes an industrialist, and when he markets his grain, in a limited sense, a trader—a trader in the ordinary sense of the word being a man who derives his profits

* *Journal of the Royal Statistical Society*, May, 1916.

from dealing with the produce of others. But, as I have said, the proposals for which I am responsible are mainly concerned with the profits which can be made for the Empire by the development of lands which, being owned or controlled by the Crown, can be dealt with without any interference whatsoever with private rights. Such realisable wealth as may be derived from, or created by, their development will be new wealth, and will be in the form of assets which, if held by the State, can be regarded as a set-off against liabilities; or, if sold the proceeds can be used either to pay interest on liabilities, to extinguish liabilities, or for general Imperial purposes.

It is interesting to note that financial problems similar to those which we are considering here are also receiving attention in Germany, where the necessity for raising greatly increased State revenues after the war is at length becoming realised. A well-known German writer has recently laid it down that "the general principle is: the more an industry lends itself to the formation of syndicates, the more suitable it is for State participation." The same writer —referring mainly to industrial syndicates— points out that the easiest way in which the State can raise large funds, is to give special positions, by way of monopoly or otherwise, to large syndicates, receiving in return a participation in their profits. He points out that by this means "the State money will be abstracted during the process of production before it has become private money." He says: "Milliards must be raised somehow, and consequently the national economic system must be hindered somehow and at some place. Wealth must unquestionably be withdrawn, the only problem is by what method. The method here indicated has the immense advantage over all other conceivable ones in that it makes for commercial and technical concentration and improvement. The self-interest of producer-associations is made to serve the interests of the State."

It is very evident from this passage that the German writer, Professor Naumann, whom I have quoted at such length, grasps the difficulty of raising the vast sums which his State will need by ordinary methods of taxation. He realises, and he is quite right, that no one likes taxation, and he, therefore, very properly casts about for some alternative plan. Even before the war the undeveloped resources of Germany overseas were incomparable with those possessed by the British Empire, and as this great source of new wealth is denied to him he very naturally looks to other forms of production, in which the State can participate directly with financial advantage to itself and without injury to the capitalists and individuals who are already engaged in them. As I have already said, I see no objection to proposals of this character which might be seriously considered in this country also with great advantage, and especially in connection with the provision of public facilities, such as electric power and means of transportation, where, owing to the uncoordinated manner in which they have hitherto been provided, an immense waste of wealth and effort is taking place. If a fresh start were made under the highest professional advice, and with the aid of State credit or funds, I am credibly informed that it would be possible for the State to derive a revenue of hundreds of millions sterling per annum, while at the same time improving the position both of producers and consumers. It is obvious that savings in cost of production have the same effect on national wealth as direct additions to national income.

Professor Naumann's dictum that the State should, so far as possible, assume the ownership of wealth before it has passed into private ownership, obviously presents no difficulty in its application, when the wealth in question is derived from land of which the State is already the owner. In this case what the State has to consider is not whether it will take wealth from the private individual, but to what extent, and on what terms, it will permit private individuals or corporations to take part in the development of State lands. From my personal experience of work of this character, I can unhesitatingly say that while the circumstances of different territories are infinitely varied, there must necessarily be sufficient similarity between the problems which they present to make it advisable to appoint a Board for the Conservation and Development of Empire Resources, and to entrust to it the task of deciding in each case how State lands and minerals can be conserved and developed with the highest benefit to the State.

It is no new thing to constitute such a Board. In this country we are familiar with the work of the Commissioners of Woods and Forests and of the Development Commissioners, who are engaged in a comparatively small way with the management of State property and with limited schemes for development. Their work might be extended in this country with great advantage, but overseas there are far greater

opportunities which hitherto have not been dealt with on sound lines, and as part of an ordered State policy. The handling of valuable assets in our Crown Colonies and Protectorates has been left to Colonial Governors and Civil servants, who are not qualified by their training and experience to settle the many complicated business questions which this work entails, with the natural consequence that the best use is seldom made of natural resources, nor is the State reaping those direct advantages which could be secured to it if a different policy were adopted.

It would be premature at this stage to define too closely the limits and character of the work to be carried out by the proposed Board. So far as my proposals are concerned it will be limited to conserving for State purposes, land, minerals, and other natural sources of wealth which the Crown owns or controls. I do not extend the word "conserve" to cover such operations as the recent purchase of the wool-clip of Australia in order to ensure that the products of the Empire shall be available in the first place for its citizens. That may very often become a highly necessary policy, but I cannot discuss it this afternoon. The Board I have in mind will have plenty of work to do without assuming, in addition, the control of the trading operations of individuals for purposes outside its primary objects, which will be directed to increasing the revenues of the Empire.

The first step to be taken will obviously be to obtain accurate information in regard to the undeveloped resources of the Empire and their possibilities. I believe that the Committee of the Imperial Institute and other bodies are now engaged in investigating these matters. Their work in this direction will be most helpful, but without some such further organisation as is now proposed much of the value of this work will be lost.

As regards the terms upon which the great Dominions might be willing to permit a portion of their natural resources to be developed by an Empire Board it would be premature and ungracious to discuss them. Where there is a will—and, above all, good will—there is always a way. Both the Imperial and Dominion Governments will have much to gain by mutually satisfactory arrangements, and to our brethren overseas the attraction presented by the prospect of early development of resources which otherwise may lie fallow for many years to come, may probably be relied on to neutralise to a very great extent calculations as to the profits which might be derived if they elected to await the time when they could develop their resources on their own account. Development gives rise to increased population, and increased population spells increased revenues and political strength. Add to these considerations a heartfelt patriotic desire to assist the Home Country and the Empire in its difficulties, and there can be no doubt as to the result.

Pending arrangements with the Governments of the Dominions, the work of an Empire Development Board must be confined to the Imperial Crown Colonies and Protectorates, to India, and to such new Colonial territories as may fall to our share on the conclusion of the war. Even in this more limited field the opportunities for successful action would be very considerable. You will not, of course, expect me to make definite proposals for action, because expert inquiry must necessarily precede such proposals. I will, however, mention to you later various promising suggestions which have been made, which may serve to illustrate the nature of the work with which it is thought that the proposed Board might concern itself with advantage.

In my recent articles I did not specially refer to the undeveloped mineral resources of the Empire which raise questions of great complexity. It is no use to be the owner of minerals of the existence of which you are not aware; it follows consequently that in dealing with its mineral wealth the State, like any other owner of minerals who does not wish to prospect for them himself, must offer sufficient inducements to private prospectors, otherwise nothing will happen. I have no time this afternoon to discuss this very complicated question at any length, and will content myself with suggesting at this stage that one of the first duties of a Board for the Conservation and Development of Empire Resources should be to consider the whole question of State-owned minerals, and decide by what means they can best be dealt with, so as to secure the maximum of benefit to the State. In the case of large deposits of iron and coal, and of other minerals of which the extent and value can be more or less ascertained at comparatively small cost, it might pay the State well to work the deposits itself. But the extent and value of the majority of mineral discoveries cannot, as a rule, be ascertained without heavy initial expenditure, and their working is usually, from a business point of view, a speculative operation. In such circumstances the owner is often well advised

in either permitting them to be worked in return for a share of the profits earned, or on payment of a rent or royalty. It is possible, however, that it might pay the State to retain the right to resume possession of any mine discovered on public land at stated intervals, on payment to the licensee of adequate compensation for disturbance, and in respect of the values disclosed by his past work.

As regards land, the means by which the State can utilise State-owned land for the purpose of meeting State liabilities are either (1) to sell or lease it in its natural state or as improved land; or (2) to use it itself as an instrument of production—*e.g.*, for the raising of stock or for the establishment of plantations. I stated in my articles my conviction that it would probably not pay the State to engage directly in ordinary agricultural operations. Land, therefore, which is primarily suitable for such operations should, I think, as a rule be sold to private individuals or corporations after such expenditure, upon or in connection with it, as may appear in each case to be justified.

Action such as I have suggested, if carried out on a large scale, will usually demand the provision by the State of a number of facilities, such as water-supplies, railways, harbours, grain elevators, and factories for the manipulation of agricultural produce, all of which should be designed to show a reasonable profit on the cost of establishing them. Some would doubtless be highly profitable. In others the margin of profit might be slender; but the general rule should be that, unless the cash value of the indirect advantages could be shown to outweigh considerably the loss to which the provision of an unpayable facility would give rise, the work should not be undertaken. As an instance of such facilities I refer to the Assuan Dam, a highly profitable undertaking, and to the Uganda Railway, which, after many years, is beginning to provide a modest return on the capital embarked in it.

I have indicated previously that the native population of our tropical possessions may properly be included in any review of our undeveloped national assets. The war has shown us the effect upon production which may be exerted by the introduction of new classes of workers into the industrial system. But whereas in this country we must look mainly to improvements in organisation and machinery to bring about increased production, we are still able in our overseas Possessions to attract large numbers of new recruits to our industrial armies, many of whom are already known to be capable of acquiring a high degree of technical skill.

How important this labour reserve, which is very largely untapped, may become is evident from the following table, which shows the areas, native populations, and external trade of a number of British Possessions in Africa, and also gives similar figures for Egypt and German East Africa.

Territory.	Area in square miles.	Population.		External Trade.	
		European.	Native.	Imports.	Exports.
Nigeria	335,700	2,600	16,258,000	6,331,751	6,779,205
East Africa Protectorate .	200,000	3,500	4,000,000	2,147,937	1,482,876
Uganda	121,437	1,017	2,904,454	897,262	524,260
Nyasaland	39,315	799	1,063,912	189,201	200,734
Gold Coast Colony . .	80,000	1,700	1,503,386	4,952,494	5,427,106
Sierra Leone	31,000	1,191	1,401,941	1,750,303	1,731,252
Gambia	4,000	149	146,101	1,091,129	867,187
	811,452	10,956	27,277,794	17,360,077	17,012,620
Egypt	363,461	221,139	12,000,000	26,583,000	35,474,000
German East Africa . .	348,318	5,336	10,000,000	2,667,925	1,777,552

The success of any proposals for the development of tropical regions will, in most cases, depend upon the extent to which native labour is available, and upon its cost and efficiency. These matters are specially important in connection with the future of our tropical Possessions in Africa. Nor can we shirk consideration of what should be our policy and methods in connection with the supply of native labour to local industries and native policy generally. The adoption of sane, just, and practical views in regard to native ownership of land and native labour is above all essential.

The problem of civilisation in new territories is to convert the indigenous native into a useful human being, to improve his value to himself and to the world at large, and to effect this change with as little hardship as possible to the individual. Similar problems have to be dealt with every day in wholly white communities, and the best solutions are found when substantial justice is done between man and man. Personally I hold most strongly that our duty, both to ourselves and to our native fellow-subjects of the Crown, lies in widening their horizons, and in offering to them all available opportunities for raising themselves in the scale of civilisation. By all means, from the point of view both of humanity and of self-interest, regulate closely the conditions and circumstances of labour, and let the State be jealous to protect the native against the cruel, careless, or dishonest employer. That, however, is a very different matter from endeavouring to prevent the natives of Africa from taking advantage of the opportunities which the spread of civilisation in their own or neighbouring British territories is offering to them.

From the point of view of self-interest also we cannot afford to neglect these matters. At great sacrifice of life and treasure we have given to millions of natives in Africa security of life and property. We can fairly claim that the natives shall in return bear their share of the Imperial burden. The native equally with the European has his duties and responsibilities to the Empire. The elimination of the slacker is as important overseas as it is here, as is also the application of the doctrine of the dilution of labour. In the best interests of the Empire and of themselves, European Colonists in tropical regions must be brought to realise that the solution of nearly all economic problems lies in maintaining the highest efficiency and the maximum of production, and that in order to attain these conditions native labourers should be trained and utilised to the fullest extent which their individual aptitudes allow. The possibilities of these regions are immense, and if their development be handled on these lines no European workman need be under any apprehension that there will be no work for him. There is always work for all in a period of rapidly expanding production.

It may be of interest to consider what the development of native territories in Africa has already added to the trade of the Empire. It may fairly be claimed, though it has been disputed, that the gold mines of the Witwatersrand could not have been brought to their present condition of prosperity by the aid of Europeans alone. These mines now produce gold to the value of nearly £39,000,000 per annum. Rhodesia has, as I have told you, a trade of about £8,000,000 per annum, of which about £6,000,000 is with the United Kingdom. This trade has practically arisen in about fifteen years, and is the result of the settlement of about 32,000 Europeans in a region sparsely inhabited by about 1,750,000 natives.

Then there are the territories of which details are given in the table to which I previously referred: Nigeria, the East Africa Protectorate, Uganda, the Gold Coast Colony, Nyasaland, Sierra Leone, and Gambia. The aggregate area of these territories is 811,452 square miles, they are inhabited by 10,956 Europeans and 27,277,794 natives, and their external trade is £34,372,697, of which far the larger proportion is carried on with the United Kingdom. Now compare their position with Egypt, where there is a total area of 363,461 square miles, a cultivated area of not more than 1,200 square miles, a native population of about 12,000,000, and an external trade of about £62,000,000. It is true that this population has been trained in habits of industry for generations. Is it not, however, obvious that the opportunities for a rapid expansion of wealth in the other territories which I have mentioned are extraordinarily encouraging, bearing in mind their numerous and various mineral and agricultural resources?

The development of each of these territories has as yet hardly begun, and it is quite impossible to forecast what their future value to the Empire's trade may become, when their resources have been further investigated and their available man-power has been better trained and organised. It must be remembered that every producer is also a consumer, and that if means be found to increase the purchasing power of the native inhabitants of our African

and other tropical territories a very valuable and expanding market will be secured for our manufacturers and merchants. From this point of view alone the State would be justified in incurring some risk in order to accelerate the development of these promising regions.

What then are we to expect of German East Africa when this great and partly developed territory has become, as I trust it may in its entirety, part of the Dominions of the Crown? In this wealthy tropical region there are, I believe, upwards of 10,000,000 native inhabitants, and its European population before the war was about 5,000. Its soil and climate are known to be suitable for the production of varied and valuable tropical products. A number of commercial estates have already been established, and data have been collected from which important conclusions can be drawn. It should offer a very promising field for State investment, and the possibilities in this direction will not, I trust, be overlooked.

It is important to note that the tropical Possessions of the Crown in Africa and elsewhere will probably never become the home of any considerable number of Europeans, who will continue to be primarily overseers of native labourers. In these circumstances there is no reason to suppose that these territories will ever receive any large measure of local self-government, and there will be the less difficulty in regarding them mainly from the standpoint of estates of the Crown which should be developed for the general benefit of the Empire, and at the same time of their native inhabitants. In such circumstances the extent to which individual European planters should be encouraged to make these territories their home will be an important question of policy to be decided in each case by the nature of the activities upon which the State itself may elect to embark. The establishment of any large central industry usually results in the creation of subsidiary industries; it is therefore quite possible that a policy such as is suggested may have the result of increasing rather than limiting the numbers of the European population, while possibly restricting the operations of large investors and corporations.

It may be added that one of the methods by which the State can derive profit from its tropical estates is to keep in its own hands the power of producing, trading in, and exporting certain special products, and especially products in which either a complete or partial monopoly can be established, such as jute and palm products. In the present embryonic condition of our tropical Possessions, all vested interests could be adequately compensated where necessary at comparatively small cost, and in the majority of cases it would be quite possible to safeguard the interests of European producers and traders without the payment of any compensation at all. These, however, are also matters which would naturally be studied closely by the proposed Board, by whom the issue of licences to trade and export would in such cases be controlled.

I have told you previously that it is not possible at this stage to lay before you any definite proposals, and before I give you some illustration of the work which the State might conceivably undertake, I should like to express my conviction that the study of markets must be an essential preliminary to action. It is not the slightest use to produce commodities for which there is not a regular, assured and increasing demand at prices which, so far as can be foreseen, will be satisfactory, or for which there are not good grounds for believing that satisfactory markets can be built up. Of the staple commodities of trade, foodstuffs must be placed first in regard to magnitude and certainty of demand; next in order come probably products required for the manufacture of clothing; next metals, minerals and mineral oils; and in the fourth place of those which I propose to mention I should place the fibres such as jute, flax, coir, and sisal hemp, which are required for so many purposes in our daily lives. I have omitted, you will see, paper-making materials. Their position in the list would naturally turn upon whether you regard our newspapers as luxuries or necessities.

It appears to me that, given favourable conditions, the State could engage with great safety and confidence in the production of many commodities which are included in the above categories. Take, for example, vegetable oils and fats, in which, if we choose to do so, we can establish to some extent a monopoly position. I ventured to suggest in my recent articles that our facilities for the production of palm products in Africa and the Pacific are so great that we might derive an income of £50,000,000 a year from these commodities alone. As the result of information which I have since received, I am convinced that my estimate was probably a modest one. In considering this question of vegetable oils and fats, I must not omit to mention the ground, pea, or monkey nut, which is destined to play an important part in

the future in the supply of those oils and fats for which even to-day all Europe is crying out, and for which it will cry still more as the populations increase and the supply of animal fats continues—as it must—to diminish. In these commodities there is a world demand, and restricted possibilities of supply. It must, therefore, be good business for us, who have the power in great measure of controlling the supplies, to engage in the business of their production on a large scale.

My next illustration, which I mention at this stage with less confidence because I am not yet satisfied that a sufficiently wide market can be developed, is concerned with one of the important fibre-producing plants, commonly known as sisal. I refer to it partly because we possess in the Empire very large areas of land which are suitable for its production, and partly because the trade figures of German East Africa show how rapidly this industry can be established. The latest report available is dated July, 1914, and states that the production for 1911 was 11,212 tons, that the crop for 1912 was about 16,500 tons, and that this figure is more than four times as great as the corresponding figure for 1908. From inquiries which I made in East Africa in the early part of 1914 I have reason to believe that the average net profit per ton can safely be estimated at from £10 to £12, so that the profit on 16,500 tons would exceed £165,000, and would thus pay interest at 5 per cent. on upwards of £3,000,000. In suitable localities this plant can be grown practically without risk, as it is exceptionally hardy and has no known pests.

Finally, I will mention a proposal which emanates from my friend, Mr. Bigland, and which has already been referred to in the press, though very inadequately, in a report of a speech which he made recently. Mr. Bigland has been impressed by the vast extent of our Empire littoral and its convenient proximity at many points to the most valuable ocean fisheries of the world. He realises, as Mr. Moreton Frewen told you here last year, that the fishing industry is probably the most productive of the large industries of the world in relation to the capital embarked in it, and to the value of the product per caput of the men engaged in it, and he suggests that the extension of the demand for fish is purely a matter of improved organisation of the machinery for distribution, and particularly in connection with the provision and use of efficient refrigerating plant. He, accordingly, believes that there is here a wide and promising field for State enterprise, and proposes that the State should take an active part in the distribution and wholesale marketing of fresh fish. Fishermen would be assisted to supply themselves with improved plant, and arrangements could be made without difficulty to protect all existing vested interests. With proper organisation and appliances it should be possible to supply the produce of the great Pacific and Atlantic Canadian fisheries to Europe, and possibly also to develop the great fishing grounds of the Antarctic. We should at the same time encourage the establishment along the coasts of the Empire of a vastly-increased number of those brave and hardy fisherfolk to whose unadvertised efforts we are largely indebted for that high degree of protection against submarines and mines which we have enjoyed during the war. Moreover, I believe that our Admiralty is at the present time in possession of the finest fishing fleet ever built. From the point of view of war insurance alone this project deserves most careful consideration. As to profits, I am not at liberty to give you Mr. Bigland's rough estimate. I will, however, permit myself to say that I greatly doubt if he would be satisfied with any less figure than the £50,000,000 at which I have had the temerity to estimate the possible amount of profits from palm products.

Nothing is to be gained at this stage by multiplying illustrations. Other suggestions of a promising character have already been made and are in course of being studied. The proposer of one of them—a large land development and settlement scheme which certainly merits most careful investigation—suggests that from this source alone the whole of the National Debt could be paid off within, say, forty years. If a very much smaller amount could be discharged by this means, I am sure you will agree that we should have every reason to be contented.

While it will be desirable, as a rule, that the proposed Development Board should concern itself mainly with large-scale enterprise, and leave to others the smaller avenues of production, it does not follow that this rule should be observed strictly in cases where several branches of production can be prosecuted together advantageously. On the principle that "many a mickle makes a muckle," the cumulative results of the cultivation of minor products might in time be quite considerable.

But you may say, "Granted that these

proposals are in the main practicable, where is the money to come from after the war to give effect to them ?" The answer to this question was given in part in my articles, in which I suggested that a portion of the Sinking Fund, which would otherwise be devoted to paying off debt, should be invested in State enterprises of the nature which I have indicated. But I also now suggest another source from which large sums might be derived, viz., the savings of the poorer classes of the community, who have hitherto had very little opportunity of making safe and attractive investments. I cannot pursue this matter deeply now, but my suggestion in broad outline is, that moneys from this source should be accepted under a State guarantee in regard to the capital, while as to interest, a minimum rate might be guaranteed by the State, and a higher rate paid, if earned, up to a fixed maximum. These investments would thus partake of the nature of participating and fully-secured debentures, the State itself being the stock-holder. I hope that after the war a Board of National Saving may be constituted to deal with these and similar matters.

Finally, you may say, "Granted that the schemes are sound and practicable, and that the money for their execution can be found, how long will it take to give effect to them ? How soon can the State expect to receive substantial benefits ?" You will readily understand that the answer to this question will probably be different in each case. Looking at it, however, from, so to speak, an average point of view, I should personally not expect large-scale results in much under ten years, though in regard to particular enterprises, some of my friends take a more sanguine view. Think, however, what a reasonable expectation of such results as I have foreshadowed would have upon the public mind, what a load of anxiety it would remove, and how greatly it would affect the policy of the country in regard to taxation. If, after close investigation by experts, it were decided that these proposed State activities could be undertaken with every prospect of success, it might even be legitimate, as I have suggested, to continue to borrow during the post-war reconstruction period, in order to relieve the pressure of taxation at a time when the nation will be least able to bear it.

That concludes the remarks which I propose to make this afternoon upon this very fascinating subject. I hope I have at least succeeded in convincing you that proposals such as I have indicated merit serious consideration, and that you will, each and all of you, do your best to see that they are not swept on one side, or rejected, without adequate inquiry.

DISCUSSION.

Mr. Alfred Bigland, M.P., who opened the discussion, said the difficulties in the way of developing our overseas resources were very great, and it was only men of sanguine temperament who could think in times of war like this of the things that had to be done in the future. He himself was one of those men of sanguine temperament who did not believe in difficulties, who did not believe in impossibilities, and who believed that the British Empire was such a marvellous asset to our race that the wonders that could be achieved were greater than had ever been imagined. The question of Socialism must be looked at in a new sense. He had always been an individualist, and had dreaded the idea of Socialism as ordinarily understood. Under the new State Socialism, however, we were not going to steal something from somebody else but were going to create wealth. Speaking of the productivity of the soil, there was no better instance than Cuba. When the Americans took over Cuba they offered £2 per ton more for sugar grown there than for any other. Immediately capital, enterprise, and labour were turned into the Island of Cuba, with the result that an annual output of 600,000 tons of sugar was in seventeen years turned into 3,000,000 tons. In Western Canada there were at least 200 million undeveloped acres which the enterprise of the British race could bring into actual work over a term of forty or fifty years. Mr. Moreton Frewen went so far as to say that even the United States would not be able to produce enough for their own population in twenty years' time, and that the British Empire could produce enough to satisfy our own needs and export to the States as well. Mention had been made of fisheries, and if there was one thing that we could legitimately take up from the point of view of Socialism it was fisheries, because nobody paid rent for the ocean. Moreover, we possessed a great deal of land alongside the ocean where fishermen could make their bases. In the Antarctic, for instance, we owned every bit of land where a fishing company could establish itself, and at the present time it was impossible to fish in the Antarctic for whales without a licence from the British Government. Along the Pacific coast of British Columbia we were in the same position. There we had a very long coast, and it was all swarming with fish. The difficulty was to get that fish to market. Some people had been going into the matter, and he believed the Grand Trunk Pacific was prepared to run special trains fitted up with refrigerating plant from Prince Rupert through to Montreal or Quebec, and from there to connect with Liverpool or London by rapid steamers. It was estimated that on the cost of

carriage alone, the fish could be delivered at 1*d*. per lb., the cost of getting the fish, of course, being extra. He agreed with Mr. Wilson Fox that it would take ten years to develop some of those enterprises, and he hoped they would not be mixed up with the Chancellor of the Exchequer and his taxation. They did not want the Chancellor of the Exchequer to say that he would tax the profits for revenue purposes. What was wanted was a Board on the lines laid down in the paper for the whole of the Empire, so that every part of the Empire could be asked to put into the hands of the Board some portion of its assets that it was not using now. When that was done we should, for instance, always be able to smoke British Empire tobacco. Jute, too, had already been mentioned. The Indian Government did not obtain much money for jute, but he would manufacture jute within the British Empire, and if anybody outside wanted it he would have to pay a very high price to get it. There was no jute grown in the world except within the British Empire. These were just a few suggestions he wished to throw out in the hope that they would be followed up.

Mr. Moreton Frewen said the world was suffering to-day from the fact that the school of economics or the school of philosophy, which was to some extent discredited to-day, was the school that they were all brought up in. He was thinking of his own days at Cambridge, when it was considered an absolute heresy to suggest that the State should do anything. He remembered crossing the Atlantic with the late Professor Herbert Spencer. The Professor talked about the infamies of State agency, and was so extraordinarily acid about the idea of the State doing anything for its citizens that he replied at last, "Professor Herbert Spencer, if I held your views I should regard it as absolutely immoral to post a letter in a State letter-box." Later he (the speaker) wrote a small book — thirty to thirty-five years ago—called "The Socialism of To-morrow," and that little book was perhaps worth recalling for this reason. He said that the line of cleavage was roughly this: that the production of wealth should be left to the individual, and the distribution of wealth, as far as possible, should be left to the State. In particular, he thought the State should undertake railroads, banking, and insurance; but it was regarded as rather a radical view at the time. However, as everyone knew, a few years later Bismarck adopted the whole of the State Socialism proposed by certain German philosophers, with such extremely satisfactory results that the problem of mere wealth had been absolutely solved in Germany. When we felt downcast at the colossal debt that the Empire was piling up at the present moment we should look for an instant at the assets of the Empire. If we could mobilise the wealth of the British Empire for the purpose of paying off the National Debt on something like the lines advocated in the paper, the debts we were incurring need not weigh in the smallest degree with any of us. He should like to say a word on the question of State ownership of railroads, which was undoubtedly one of the questions that were coming up for solution. Some twenty-five years ago the Hungarian Government reduced the third-class fare from one penny per mile to one penny for three miles. Some railway experts thought the extraordinary State experiment would be a failure. During the first year there was a small loss, but the year after that the Hungarian State railways earned more profits than they ever did before. It also enabled the population of the mountainous districts to get down to the rich Danubian province to gather in the harvests, and then to return to vivify the whole life of the villages. Something of the same kind happened when the first railway was built from Ottawa. The Canadian Pacific people were told that nothing but disaster could follow the building of a railway into the inaccessible regions. But what happened? The earnings of the Canadian Pacific were then ten million dollars a year; to-day they were 140 millions. Mr. Bigland had mentioned fisheries. Last year he himself read a paper before the Society on the State and the fisherman, and pointed out that in other countries, where the fisheries were less important and infinitely less valuable than ours, the State was spending large sums of money, with the result that the men who worked for six months in this industry were, in the United States and Canada, earning twice as much as the men who worked twelve months on the land. Canada was spending ten times as much on her fisheries as we were spending here, and the United States twenty times as much. The removal of the shad fisheries from the Atlantic to the Pacific by the United States had resulted in the creation of enormous wealth, the waters for 3,000 miles of the Pacific were alive with this valuable food fish. In this country we had got into a ruck of individualism, or were so weighed down by Herbert Spencer and a crowd of philosophers, that we had done nothing with our assets. Really, he almost felt that Germans were justified in starting this infamous war when they saw how, enjoying all the best of the globe, we had done so little to develop it. The whole conduct of statesmen in this country for fifty years had been nothing short of criminal.

Mr. J. W. Stead asked if Mr. Fox was in favour of the nationalisation of mines, the nationalisation of the railways and canals, the displacement of the Post Office system, and the nationalisation of life insurance, as supplementing the new acquisition of wealth from the sources he had mentioned. Further, had private production proved a success during the war, and was the increased wealth to be distributed in a more equitable manner than at present? Finally, were we now fighting for territory, because Mr. Fox had said we were going to keep German East Africa. Were we fighting for territory or justice?

The Hon. Sir John McCall said the chief and most important part of the paper related to the use of the undeveloped resources of the Empire for the purpose of paying off the debt incurred during the war. The other matters that had occupied the attention of the various speakers could be left over for the present. He thoroughly endorsed everything that had been said on this aspect of the question, and there would not be, in his opinion, the slightest difficulty in finding the men to manage the various concerns that must of necessity come into existence. In the Colonies and the Dominions they had managed their own railways for quite a long time, and no difficulty had been experienced in securing able men to work as Commissioners of Railways. Similarly, the men who had so successfully managed private industries could do equally well for the State. Furthermore, private individuals investing in industries usually looked for a return of from 8 to 10 per cent., whereas the State would no doubt be able to raise the necessary capital at 4 to 4½ per cent. The Chancellor of the Exchequer ought to find the money for the new Board which it was suggested should be formed.

Mr. T. L. Gilmour, who was a member of the National War Savings Committee, said Mr. Wilson Fox had asked him to say something on the work of that body with particular reference to the suggested National Savings Board after the war mentioned in the paper. There was evidence that many of the public had very little idea of the work the War Savings Committee was really doing. That Committee was asked by the Government to do two things: in the first place to undertake a campaign throughout the country for reducing expenditure upon things that were not necessary—and many probably only knew the Committee in that capacity—and, secondly, to establish throughout the country War Savings Associations for the collective purpose of Government securities and mainly for the wonderful Government security known as the "£1 for 15*s*. 6*d*." certificate. The Committee had now been engaged upon this work for several months, and had called in the aid of the local authorities throughout the country. The organisation so established was distinctly temporary, so far as its immediate object was concerned, viz. to raise money to assist in the prosecution of the war, but he thought it could be adapted on the lines suggested by Mr. Fox. Up to the present date there had been established in England and Wales—the Committee did not cover Scotland and Ireland—838 committees, one to each borough of over 20,000 inhabitants. Other committees had been formed in smaller boroughs, and there were also a number of county committees. The main object was to appeal to the small investor, and there had been established 15,758 War Savings Associations which had sold 50,988,381 "£1 for 15*s*. 6*d*." certificates. At the same time through the Post Office, and in other ways, £9,453,380 worth of 6 per cent. Exchequer bonds had been taken up—all contributions from the small investor. The total contribution of the small investor since August 1914 amounted to £111,176,000 in 4½ per cent. loan, 5 per cent. bonds, and war certificates for small amounts. This showed that there were large untapped resources available for the provision of capital for the purposes indicated in the paper. In France and other Continental countries the small investor was very well known, but in this country we could not claim in the past to have been a very thrifty people. At any rate we had not formed the habit of investing, and in this connection he ventured to think that the War Savings Committee was doing work which would extend far beyond the war. Habits were now being acquired by the working-classes of this country which he was quite certain would remain with them in the future.

The Hon. J. G. Jenkins asked Mr. Fox if he had considered the question of funding the whole of the Imperial war debt at the conclusion of the war? The Dominions were incurring a large war debt on their own account at a rather high rate of interest, and we also were incurring a large debt at a high rate, and the funding of all these debts was a subject worthy of notice.

Mr. Wilson Fox, replying to the last question, said it was premature at this moment to come forward with any considered ideas with regard to pooling war debts. There must be a conference to deal with all these matters arising between the Imperial Government and the Dominions, and we must not approach this question with ideas too much crystallised. Consequently all he had said in this connection had been purposely nebulous. From the financial point of view there was a great deal to be said for pooling; but he would be sorry to say anything that might have a prejudicial effect upon future arrangements. Replying to Mr. Stead's questions, he said he was dealing primarily with economical and not political questions, and also with the question of dealing with our undeveloped resources. He had suggested, however, that he was not personally against State action in other directions, if the State saw its way to make money out of it, and if, in doing so, the Government did not interfere too much with general industry and individuals. He had also suggested that these matters would have to be considered by a Board of experts, and he did not profess to be either a Board or an expert. Therefore he did not think he could answer these somewhat difficult questions, many of which were highly controversial. One of the questions, however, was easy to answer, viz. the one in which he was asked how the results of State action would be distributed. He did not think the State would distribute it at all, because if it succeeded in making money it would put it in its pocket, and use it for State purposes. As individuals the public would not get a dividend,

although that might come in time, but he did not have that in mind at present. The best that the public could hope for to begin with was fewer calls by the State in the way of taxation. As to whether we were fighting for territory, he did not think it necessary to decide that in principle, but if at the end of the war we found ourselves in possession of the whole of German East Africa, and we did not get sufficient indemnities to pay us for everything that the war had cost us, he had no objection to our remaining in possession of German East Africa. He regarded the matter from the commercial point of view. He did not see why we should be out of pocket if we could force Germany to put us in a better position.

The Chairman (The Right Hon. the Earl of Selborne, K.G., P.C., G.C.M.G., D.C.L., LL.D.), in proposing a vote of thanks to Mr. Wilson Fox, said he was one of the brilliant group to which Mr. Moreton Frewen and Mr. Bigland belonged, who, at a time when our statesmen could not possibly think out these questions and were wholly occupied in the business of the war, had come forward with a series of probably the most pregnant suggestions that had been put before the British public on the subject of Empire economics within the last century. It was very refreshing to hear Mr. Moreton Frewen's onslaught on the utilitarian philosophers and the politicians who for so many years had been bemused by their doctrines. All the points put forward in the paper deserved very careful consideration; they suggested the difficulties which had to be met, and the questions which must be studied, and none of the criticisms could be regarded as an effectual barrier to a consideration of the great questions that had been indicated. We must be prepared to face the future—political, social, and economic—divested of all the prejudices which had gathered round us, no matter to what party we belonged. The whole of the circumstances of the country, the Empire, and the world were going to be different from what they had been before, and there would be no chance of successfully coping with these circumstances if we allowed ourselves to be trammelled by the shackles of opinions and prejudices which we had inherited from thinkers of the past, who never had to deal with circumstances in any sense parallel or analogous to those with which we now had to deal, and of which they, in their wildest moments, never contemplated the possibility. All the problems set out in the paper were at present only in the stage of suggestion, and the amount of thinking that had to be done to bring them to useful fruition was very great. Nobody was more conscious of that than Mr. Fox and his associates, and he personally regarded that meeting as a distinct step—not the first, or even the second, but perhaps the third step—in the study of this problem.

The vote of thanks was unanimously passed.

ENGINEERING NOTES.

A Russian Canal.—The rivers of Russia, though they are the longest in Europe, have a most sluggish course and flow into the inland seas for the most part. They rise in the great Russian central plains, and for that reason present great opportunities for work in the direction of canals and canalisation. A scheme at present in hand was planned to cost £16,700,000. The idea is to make a great canal, divided into portions. The first was to consist of the regulation of the western Dwina from Riga to Vitebsk, and was to be 360 miles in length. The second portion was to be the canal proper from Vitebsk to Orsha on the Dnieper, fifty-two miles long. The third and southern portion would be the regulation of the Dnieper from Orsha to Kherson, 1,055 miles long. In all the canal would, when complete, be 1,473 miles. It will be at once perceived what an immense gain to Russia the proposed canal will be when constructed. It will traverse her richest agricultural district, and greatly facilitate the export of her grain. The chief towns upon this waterway include several important centres. These export, among other items, grain, timber, flax, naphtha, petroleum, sugar, tobacco, fruit, and vegetables. What the country wants mostly is agricultural machinery and manures. Germany has hitherto supplied Russia with these; it remains for Britain to do it in future. The economical and strategical value of this canal is concentrated in one fact—it would to a great extent make Russia independent of the Dardanelles. Goods would pass in twelve days from the Black Sea to the Baltic. Some progress has been made with the canal. In the summer of 1913 a good deal was done between Ekaterinoslav and Gradizkok in the way of blowing up submerged reefs and obstructions to small rapids, and deepening river beds. A large sum of money was allowed for this portion of the work, and it was expected to take four years. The deepening of the river between Ekaterinoslav and Kiev has been commenced. From Kiev to Orsha the banks have been strengthened and the channel deepened. In the Vilna district a fresh canal has to be made from Orsha to the Dwina. On the Dnieper from Alexandrovsk to the sea the canal is ready for use. Had the whole canal been ready for use, how greatly it would have aided Russia just now. The above has been abridged from an article on the general subject of internal water communications of Russia in *Chambers's Journal*.

Power from a Volcano in Tuscany.—This remarkable installation, giving power by the generation of natural steam, is described by Professor Luiggi, D.Sc., M.Inst.C.E., in *Engineering*, and is briefly as follows. As is well known, in Central Tuscany, near Volterra,

there are numerous cracks in the ground, from which powerful jets of very hot steam spout high in the air with great violence and constancy, bringing up boric acid, which is very valuable, and other mineral substances of less importance. These powerful jets of superheated steam are called *soffioni*—the "blowers"—and have been utilised for many years in the production of boric acid and borax, and occasionally for warming the houses in the near-by village of Larderello. The larger proportion of the steam, however, is lost, having no local application, and with it is lost its very valuable heat. Prince Ginori-Conti, the President of the "Società Boracifera de Larderello," tried to get a more ample supply than is afforded by the borax works, by boring holes in the ground, lined with iron pipes, driven down to the very source of the steam, which is under a hard stratum of rock about 300 to 500 ft. below the surface. These bore-holes vary from 12 to 20 in. in diameter, and give forth steam with a pressure from 2 to 3—and, exceptionally, up to 5—atmospheres, and at temperatures varying from 150° C. to 190° C. For several years these jets have not diminished in their capacity, nor does a new boring seem to interfere with the preceding ones, provided the distance from one to another is not less than 50 ft. Acting on the advice of the Tosi Works, of Legnano, specialists in steam turbines and alternating electric generators, he ordered three groups of condensing turbo-electric engines, each of 3,000 kw., working with superheated steam at 1½ atmospheres, generated in specially constructed multitubular boilers, the latter arranged vertically and with aluminium tubes, both for better utilisation of the heat and better resistance to the corrosive action of the natural steam from the *soffioni*. This steam, it is worth while to repeat, is used instead of combustible; it loses part of its heat in the boiler, reducing its temperature from 180° C. to about 120° C., and is then utilised for the borax industries. The steam thus generated in the boilers and used for the turbines is ordinary water steam, which on its way to the turbine passes along aluminium pipes heated outside by a current of superheated natural steam, at 180° C., and thus gets in its turn superheated to about 150° C. After passing through the turbine this steam is discharged into a surface condenser, the circulating water of which is in its turn cooled in an ordinary cooling tower. The condensed steam from the turbines is, of course, pumped back into the boilers, and thus no natural steam ever comes in contact with the turbine. The tri-phase electric current is generated at 4,500 volts and 50 periods per second, raised up through an oil transformer to 36,000 volts, and sent along aerial conductors to Florence, Leghorn, Volterra, Grosseto, and many smaller towns of Tuscany, to be principally used as motive power for munition works during daytime and partly for lighting purposes at night. One of the 3,000 kw. units has been at work since January 1916, the second since April, and the third has just been started. So far, the first two groups have worked quite successfully, and have been a great boon to the industries of Tuscany, greatly crippled by the scarcity and high price of coal. This very successful harnessing of volcanic heat to an electric power-house can be increased practically to hundreds of thousands of horse-power, as the region of the *soffioni* extends for many square miles around Lardello. Similar installations to the above are contemplated near Naples, where there is another large area giving out steam.

Wireless Telegraphy on Aeroplanes.—According to American reports, says the *Wireless World*, what is claimed to be a record in wireless telegraphy from aeroplanes was recently established by Captain Culver, of the United States Aviation Corps. During a flight from San Diego to Santa Monica, 114 miles away, he is stated to have kept in touch with his station by sending wireless messages every three minutes. The power for the transmission set is derived from a generator placed on the lower wing section of the aeroplane, and is driven by a two-bladed propeller. Aerial wires are suspended from the "fuselage" of the machine, with an insulated counterpoise hung from the wings to the tail of the aeroplane. The complete transmission set is stated to weigh less than 40 lb.

OBITUARY.

William Wallace Blair.—Information has been received of the sudden death from heart failure of Mr. William Wallace Blair, of Victoria, British Columbia, at the age of sixty-four.

Mr. Blair was a native of Tyrone County, Ireland. He went to Canada, and about twelve years ago established himself at Winnipeg, where he followed the profession of architect. As a member of the Royal Architectural Institute of Canada he was widely known in the Prairies. He settled in Victoria about two years ago and retired from practice.

He was elected a Fellow of the Royal Society of Arts in 1909.

NOTES ON BOOKS.

The British Empire at War. By Urban H. Broughton, M.P. London, 1916.

In this little brochure of fifty small pages Mr. Broughton describes briefly, for the benefit of his numerous friends in America, the principal steps taken by the British Empire in the conduct of the war. In surprisingly few words he gives a clear account of the present state of the army,

the navy, the air services, the tremendous work of the Ministry of Munitions (which, at the time of writing—September 1916—controlled 4,319 firms and 2,250,000 employees), finance, trade, and our mercantile marine.

Mr. Broughton certainly makes out a very good case for the part taken by us in the war, and it is no doubt desirable that neutral nations should be made aware of what we have done. We believe that he could have made the case even better had he dwelt a little longer on the auxiliary services we have been rendering to our Allies—such facts, *e.g.*, as that we have furnished the French armies with 10,000 miles of telephone and telegraph wire, and that the very stones used for repairing the streets in Northern France are sent over from England. No doubt, however, the author was embarrassed by the wealth of his material, and he has certainly managed to compress a great amount of information into a very little space.

WIRE AND SHEET GAUGE TABLES. Compiled by Thomas Stubbs. London: E. & F. N. Spon, Ltd. 3*s.* 6*d.* net.

These tables have been compiled for the use of merchants, manufacturers, and those connected with the wire, sheet steel, and other metal industries. The book contains English, metric, and foreign sheet gauge tables, with net and gross divisors for finding out and working weights, allowances for mill scrap, etc.; it also gives the weights of all sections of precious and common metals, and English and metric weight and measure tables, with their equivalents. The calculations have been made with great care, and so far as we have been able to test them, the figures are accurate. As a metal calculator and ready reckoner the tables should prove very useful for office and shop use.

GENERAL NOTE.

STANDARDISATION OF CARGO VESSELS.—A pamphlet has been issued by the United States Department of Commerce, entitled "Standardisation in the Construction of Freight Ships," and is intended to encourage the building of vessels for the foreign trade of the United States. It was written for the Department by Mr. E. P. Stratten, Consulting Engineer of the New York Board of Underwriters and formerly Supervisor of the American Bureau of Shipping. The author states that he finds in the United States signs of a disposition so to standardise the construction of cargo types of steamships as greatly to reduce their cost. He believes that the successful development of this tendency will go a long way towards making the United States entirely independent of other countries in the construction of ships for its foreign commerce. Details of construction are discussed, and it is proposed that the country's great steel plants develop a thoroughly well-standardised system of supplying dimension materials, shaped and punched, ready for assembling in the hull of any standard ship of specific dimensions. Copies of the pamphlet may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D.C., at a cost of 5 cents (2½*d.*) each.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

DECEMBER 20 (at 4 p.m.).—A. C. BENSON, C.V.O., Master of Magdalene College, Cambridge, "Classical and Scientific Education." THE RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

JANUARY 24.—W. A. M. GOODE, Hon. Secretary, National Committee for Relief in Belgium, "Relief Work in Belgium."

JANUARY 31.—MISS ELLA C. SYKES, "The Work of the Y.M.C.A. in France."

FEBRUARY 7.—ROBERT FORTESCUE FOX, M.D., "The Future of British Spas."

FEBRUARY 14.—LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

Dates to be hereafter announced:—

JAMES HARRIS VICKERY, LL.B., "German Business Methods."

CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

OCTAVIUS C. BEALE, "British Arts and Crafts after the War."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel."

SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

January 18, February 15, March 15, April 19, May 17.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

January 30, February 27, March 27, May 1.

HOWARD LECTURES.

Monday afternoons, at 5 p.m.:—

WILLIAM RIPPER, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m.:—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 6, 13, 20.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

ALAN A. CAMPBELL SWINTON, F.R.S., "Electricity and its Applications." Two Lectures.

January 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 18...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. J. Thorp, "Order in the Modern City, and London in Particular."

Bibliographical Society, 10, Hanover-square, W., 5 p.m. Mr. S. Wheeler, "Notes on the Bibliography of Landor."

British Academy, in the Theatre, Burlington-gardens, W., 5.15 p.m. (Schweich Lectures.) Professor L. W. King, "Legends of Egypt and Babylon in Relation to Hebrew Tradition." (Lecture II.)

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. R. H. Compton, "New Caledonia and the Isle of Pines."

Faraday Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. 1. Messrs. R. G. Parker and A. J. Dalladay, "On a Precision Method of Uniting Optical Glass—the Union of Glass in Optical Contact by Heat Treatment." 2. Dr. W. C. McCullagh Lewis, "The Effect of Pressure on the Equilibrium Constant of a Reaction in a Dilute Solution. A simple proof of the expression." 3. Mr. E. D. Campbell, "Do Equiatomic Solutions in Iron possess Equal Resistances?" 4. Mr. R. H. Sherry, "Grain Growth in Deformed and Annealed Low Carbon Steel." 5. Messrs. E. Griffiths and E. A. Griffiths will describe and exhibit a New Electric Furnace for testing the Softening Points and Compressive Strengths of Refractory Materials.

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Sir Guilford Molesworth, "Indian Weights, Measures, and Money."

TUESDAY, DECEMBER 19...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. S. L. James, "Notes on the Subject of Geological Mapping."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Mr. G. Drage, "The Reorganisation of Official Statistics and a Central Statistical Office."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Discussion on Mr. P. M. Crosthwaite's paper, "Experiments on Earth-Pressures."

Colonial Institute, Hotel Cecil, Strand, W.C., 4 p.m. Miss Edith Browne, "Possibilities for British Trade in South America after the War."

WEDNESDAY, DECEMBER 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Mr. A. C. Benson, "Classical and Scientific Education."

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Mr. C. Salter, "The Measurement of Rainfall Duration." 2. Professor H. H. Turner, "Discontinuities in Meteorological Phenomena." (Third Note.)

Microscopical Society, 20, Hanover-square, W., 7 p.m. 1. Professor Sydney J. Hickson, D.Sc., F.R.S., "Certain Sessile Forms of Foraminifera." 2. Mr. A. Bacot, F.E.S., "Note on the relation between the Hatching and Development of the Larvæ of the Yellow Fever Mosquito, *Stegomyia fasciata*, and the presence of Bacteria and Yeasts."

THURSDAY, DECEMBER 21...British Academy, in the Theatre, Burlington-gardens, W., 5.15 p.m. (Schweich Lectures.) Professor L. W. King, "Legends of Egypt and Babylon in relation to Hebrew Tradition." (Lecture III.)

Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. G. Senter and G. H. Martin, "Studies on the Walden Inversion. Part V.—The kinetics and dissociation constant of a bromo-β-phenyl-propionic acid." 2. Messrs. R. H. Pickard, W. Lewcock, and H. de Pennington, "The alcohols of the hydro-aromatic and terpene series. Part III.—The isopulegols corresponding with l-menthol and d-neomenthol." 3. Mr. H. G. Denham, (a) "Lead sub-iodide with details of the preparation of lead sub-oxide"; (b) "Note on the solubility of lead iodide." 4. Messrs. A. F. Joseph and W. N. Rae, "Chromium Phosphate."

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. C. Robbins, "Odds and Ends."

Historical Society, 22, Russell-square, W.C., 5 p.m. Rev. Claude Jenkins, "The Historical Manuscripts at Lambeth."

Numismatic Society, 22, Albemarle-street, W., 6 p.m.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Professor H. Adams, "Pile Driving and the Supporting Power of Piles."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. W. H. Goodchild, "The Economic Geology of the Insizwa Range."

FRIDAY, DECEMBER 22...Colonial Institute, Hotel Cecil, Strand, W.C., 3.30 p.m. (Juvenile Lecture.) Mrs. Blount, "British East Africa and Lake Victoria Nyanza."

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—December 15, 1916.

Journal of the Royal Society of Arts.

No. 3,344. VOL. LXV.

FRIDAY, DECEMBER 22, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

INDIAN SECTION.

Thursday afternoon, December 14th; The RIGHT HON. LORD EMMOTT, G.C.M.G., and subsequently SIR WILLIAM DUKE, K.C.S.I., K.C.I.E., Chairman of the Indian Section Committee, in the chair. A paper on "The World's Cotton Supply and India's Share in it" was read by MR. JOHN AITON TODD, B.L., Professor of Economics, University College, Nottingham.

The paper and discussion will be published in the next number of the *Journal*.

JUVENILE LECTURES.

A Member of the Council, Mr. Alan A. Campbell Swinton, F.R.S., has kindly undertaken to deliver the Juvenile Lectures this year on "Electricity and its Applications." The lectures will be delivered on Wednesdays, January 3rd and 10th, at 3 p.m. They will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SIXTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 20th, 1916; The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society;—

Boag, George L., Aguilas, Murcia, Spain.

Lovejoy, Frank W., 1438, Main-street, Racine, Wisconsin, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Baker, George Percival, Ivydene, Cold Blow, Bexley, Kent.

Heap, Arthur Cecil, Vickers House, Broadway Westminster, S.W.

Knight, Berkeley, Bradley, Overton Drive, Wanstead, Essex.

Wagner, Orlando Henry, M.A., 90, Queen's-gate, S.W.

THE CHAIRMAN, in introducing the reader of the paper, remarked that it was often said that education was a singularly dull subject. Whether that was due to the fact that the controversies which concerned it very often turned upon well-worn themes, and concerned themselves with administrative details which were apt to be dry, however important; or whether it was owing to the fact that education was a subject of such an immense number of commonplace remarks, which were not so far from the truth that it was possible to contradict them, but which at the same time very seldom seemed to hit those real underlying principles in which the subtle truth and essence of education were placed at their practical value, he did not propose to inquire; but he could promise the audience that it would not be dull on the present occasion. Mr. Benson's name and fame were well known, and he had had an educational experience of unusual variety. He had seen education from every conceivable point of view—as an under teacher and as a head teacher, as the Don of a college and

as the Head of a college, and as a writer upon educational subjects in many forms; while his charming essays, in which he had treated both of education and of many other subjects, were well known and read with constant and fresh enjoyment.

The paper read was—

LITERATURE AND SCIENCE IN EDUCATION.

By A. C. Benson, C.V.O.,
Master of Magdalene College, Cambridge.

There is a very amusing caricature by Mr. Max Beerbohm of the poet Coleridge in his later days, when he lived at Highgate, planned important books in many volumes—not a line of which was ever written—and talked philosophy to all who cared to come and listen. The picture represents Coleridge holding forth in a deep abstraction, with his eyes fixed upon the Absolute, and the guests all asleep—not politely and decorously slumbering, but plunged in a lethargy so profound that they are heaped up against each other, like a bundle of sausages. Such, strange to say, is the sort of effect often produced by those who venture to discourse at large upon education. The strangeness lies in the fact that education is almost the only subject in which almost every man feels himself to be an expert, and claims the right to hold and express an opinion. Yet it is admittedly a dull subject, and, perhaps for that very reason, that all feel equal in discussing it. The expert contemns the amateur, the amateur mistrusts the expert. I myself have had a fairly wide experience of education. I was a public school master for twenty years, and I have been a Don and College lecturer for twelve more. I have been a diligent member of a county education committee for a good many years, and I have sat on every single sub-committee at various times. I am on three school governing bodies, a public school, an urban day school, a county grammar school, and I have been for some time on the governing body of a teachers' training college, besides being for a period on the consultative committee of the Board of Education. These are my credentials for addressing you; and I may say that I have come to the conclusion that the practice of education is one of the most interesting things in the world, and the theory of it one of the dullest, for the reason that it reduces itself mainly to very minute and complicated questions of finance.

The fact is that in England we have tackled the matter of education from the administrative side, and, like true-born Britons, we have had a deep suspicion of the philosophy of it. What is the aim of education? That is the one question to which we have never attempted to give an answer. Is it to prepare a man for earth or for heaven? Is it to train the character, or the imagination, or the intellect? Is it to turn out good citizens, or wage-earners, or well-informed men, or practical men, or healthy men, or men of culture, or idealists? What we have certainly contrived to do, without any apparent aim, is to train a generation eminently fitted by devotion and public spirit, and self-sacrifice and bravery, and discipline and cheerfulness, to become in an amazingly short time a generation of excellent soldiers. And in reforming our education it would be worse than childish to overlook that. In spite of all strictures, we have produced the right article at the right moment, and it is a result of which we have every right to be proud.

Personally, I believe that the aim of education is primarily the training of character, and in this respect I believe that we may be said to have succeeded far beyond reasonable expectation or unreasonable hope; and whatever we do to alter our education we must contrive to keep that ethical element. Intellectually, we have not done so well. We have not succeeded in kindling intellectual interest, and I further believe that we have not made the most of our resources of definite technical ability. The framework of a system is all there, but we have not taught the right things, or we have not taught them in the right way; we have not sufficiently developed individual capacity; and I believe that the reason why we have not succeeded here is that we have not sufficiently recognised the differences of temperament and taste. We have compromised, because we have begun with the notion that it is possible to find a type of education which is applicable to all alike, and what we have called a sound general education has not been a sound one at all, and only general in the sense that it suited no one in particular. It is just as if we had invented a sound general diet by trying to cater for all digestions and appetites, man, woman and child alike, without recognising the vast differences in human nature and the nuances of human inclination.

Every practical educator knows that one can divide one's material into three rough classes. At the top come the people, not very numerous, of strongly-marked individual capacity and

ability. These can often deal fairly successfully with a variety of subjects, but there is generally one subject in which they are obviously and specially proficient. I will take the third class next, and these are the people who are clearly slow and dull, and find great difficulty in applying themselves intelligently to any subject at all. Then there is a much larger second class of fair straightforward capacity, not markedly good at any one subject, and yet not markedly feeble; and it is these who are the chief problem. The first class need careful special training; the third class are probably not adapted for an intellectual education at all. The second class are really the difficulty.

The new scheme of the Board of Education is probably the best attempt which has yet been made to deal with the situation. It amounts to this: that up to the age of sixteen or thereabouts boys should be taught the things which no one can well dispense with—English, a foreign language, elementary mathematics, elementary science, history, geography, scripture, and if possible a handicraft of some sort. By the age of sixteen it is generally possible to discern an aptitude of a definite kind. After that age, then, a boy should be enabled to give a little more time to his particular aptitude, not simply specialising, but providing a sensible balance. Then, it may be hoped, the universities will be more elastic in giving to all boys, who are capable of profiting by higher courses of study at all, a chance of pursuing a special subject. Thus, it is suggested, we might turn out men who really had a subject, and moreover had the simple accomplishments necessary for efficient work in the world.

But now we come to a more difficult part of the subject. What on the whole should general education aim at? Education used to be divided into ancient and modern, the classics forming the bulk of the ancient, and modern languages with science being included in modern education. But it is clear now that this is a wholly false division. The true division is literary and scientific; and this must be considered more in detail.

The old theory of humanistic education, as it is called, was simple enough. It was an attempt to train the mind in the best that had been thought and said in the world, instead of on a subtle but arid theology. It consisted of poetry, philosophy, and rhetoric, and was based on classical literature; but it must be remembered that there was then no science at all, very little history, no geography or ethnology to speak of, very little modern literature, and little mathematics. It was partly moral and partly intellectual, and it aimed at fortifying and refining the mind.

It was not really till the nineteenth century that the modern and scientific subjects began to claim attention, and it all came with a rush. Scientific discovery, exploration, pure and applied mathematics, modern literature, all began to accumulate results and conclusions of startling import. But the old order was so firmly rooted, that it was not until some fifty years ago that these later subjects began to creep into the curriculum of schools; ever since that date there has been a steady struggle. Subject after subject forced itself in, while the old guard, the classicists, disputed every inch of the ground. The result has been a hopeless congestion, and the elements of so many things have had to be taught that only the cleverest boys contrived to assimilate what may be described as an intellectual kedgeree. Now we have come to the point when it is obvious that everyone cannot learn everything, and what we have to do is to settle a very simple core of education, providing enough variety to detect aptitude, and, as soon as aptitude is pronounced, to enable it to be cultivated.

But the danger at the present moment is this, that the classical system, thrust into a corner by modern subjects, provided so desolate and tough an education, concerned as it was with such a mass of grammatical niceties, anomalies, syntactical peculiarities, that it had not a chance itself of enlightening or encouraging its victims, and yet, by claiming so much time, kept the other subjects all in elementary stages too. The impatience and the rebellion produced by this reactionary and stagnant system have risen to such a pitch, that we are in danger of arguing that, because the classical system has failed, therefore literature has failed. I have been reading a vehement little pamphlet lately in which the author speaks of feeling "a grave concern as to the triviality of the literature to which the education of the present day leads; so much about the failings and foibles of human nature, so little about the majestic and inexorable laws of the physical side." Such reformers as these say, "For goodness' sake, let us have an end of all this nonsense; instead of feeding the minds of boys upon old human visions and fancies and imaginations, let us feed them with realities. Let us teach boys something about the world in which they have to live." With

this attitude it is impossible not partly to sympathise. But the danger, as I say, is that we may simply substitute one tyranny for another. I was always very anxious for elasticity, and worked hard for many years to break down the rigours of the classical system; but it was all in the interest of elasticity and special aptitude. I do not want to turn out the old system neck and crop, simply to introduce another system just as tyrannous and just as neglectful of temperament and aptitude.

Human perception and intelligence is somewhat sharply divided. Some minds are abstract, others concrete. Some minds are interested in ideas, in beauty, in old traditions and memories, in human adventures and experiences, in religion, in political theories, in the slow organisation of communities, in problems of government, in schemes of social reform—in everything in fact which deals with human temperament and character. Other minds are interested in more concrete things, in the phenomena of nature, properties of matter, substances, machines, contrivances, manufactures, applied science generally, by which the laws of nature are used to serve human welfare and convenience. Both these sides of life are entirely worthy of study and attention, neither is negligible, and it is worse than childish for either type of mind to allege that the preferences of the other type are unimportant.

A literary education, as it is called, is a study of all that deals with the emotions, hopes, fears, desires of mankind, and to some minds these are the transcendently important realities of life; a scientific education deals with man's material environment; and as man is a spiritual being living under material conditions, it is of the utmost importance that both should be studied and realised.

Such a statement as that which I read just now, about "a grave concern as to the triviality of the literature to which the education of the present day leads; so much about the failings and foibles of human nature, so little about the majestic and inexorable laws of the physical side," is palpably onesided.

It appears to me, in the first place, a very unscientific position to take up; for surely "the failings and foibles of human nature" are just as much scientific facts as any other thing, just as much the outcome of the "majestic and inexorable laws" of nature as any physical fact. Considering how much of science has been constructed out of the patient study of innumerable details, apparently very trivial in themselves, it is clear that the failings and foibles of human nature are, at least, as worthy as all other details of scientific consideration.

And then, too, human nature as acted upon by the inexorable physical laws is the thing, after all, which concerns and interests us most. It is true that we have to live in a physical universe and we must recognise physical laws. But a minute study of those physical laws must always be a matter for specialists. The ordinary human being has not time or intelligence to go far in the direction of scientific research, while the whole of his life is spent in contact with human nature, and its faults and foibles. It is far more important for the ordinary human being to know something about human nature than to know about ocean currents and tides, about light and heat, about stars and meteors. The only part of scientific knowledge which is of practical concern to most human beings is the elementary facts of physiology. And the practical effect of learning about the heroic possibilities of human nature, being moved by stories of courage and patience, of pity and affection, is far deeper and greater than the effect of learning about the motions of planets or the origin of storms, because none of us can escape from the problems of human nature, affecting our daily conduct and our relations with other men, learned and unlearned alike; while the properties of matter, the laws, let us say, of electricity or chemistry, are at best remote from daily life, and can only be apprehended and applied by experts. All of us, for instance, know what it is to be affected by the look of anger or affection in a fellow-creature's face; while the fact that we can only see it because a combination of carbon with oxygen produces an undulatory vibration in the ether which is luminous is not a consideration which can ever have a very wide appeal. For even when we know *how* it happens, we are not much nearer to knowing *why* it happens.

And then, too, the greater part of civilisation and progress depends not upon the scientific discoveries which add to the comforts of life, but upon the cultivation of generous motives, of disinterested sympathies, of desire for justice and order and co-operation. Human happiness is far more knit up with the art of living peaceably and affectionately with other human beings than with the inexorable laws of matter. Birds and beasts live in the universe without any scientific knowledge of its laws, but with much instinctive and precautionary acquain-

tance with them. A bird knows what food it needs, and what is dangerous, without having an idea of why it needs food, or why a course of action is dangerous; and the importance of literature is that it develops the imagination and sympathy of man, while science may perhaps cultivate imagination, but can hardly be held to develop sympathy.

I am wholly in accord with the desire to teach human beings something about the wonders of the physical world in which they live; but to turn our back upon human nature, its hopes and fears, its visions and dreams, its sins and failures, seems to me to be the most short-sighted policy. We are not yet all abstract intelligences; we are imperfect beings living in communities. Character rather than intelligence is the real aim of education, and if that is so, then "the proper study of mankind is man."

The real difficulty of the whole position lies in our vagueness of aim: we do not really know, and we have never troubled to decide, what we desire the educational process to do for our children. My own belief is that it is a threefold aim. In the first place, education should be elastic enough to enable us to discover aptitude and capacity, and therefore we want variety. The mistake of the classicist is that his ideal education is only a device for discovering literary ability, and the mistake of the modern reforming scientist is precisely the same; a scientific education is a device for discovering scientific capacity. What we need is a method of finding our future experts, for it is of the utmost importance to the race that we should discover, evoke, and use every sort of intellectual ability. What we need is an education both literary and scientific, dealing with ideas and emotions and imaginations as well as with perception and observation and exactness of mind, so that at the time when vocation begins to declare itself we may skim the intellectual cream, so to speak, and set free the best abilities and capacities to pursue their own bent. That is the first aim of education, the discovery of aptitude.

The next aim of education is a wider and more general one: it is to reveal as far as possible to the growing mind a real idea of the conditions under which it lives and will have to live. Science is an integral part of such an education, and general knowledge of physical laws and processes is of primary importance. The stars we see above us, the physiography of the globe, the laws of electricity, of weather, of heat and cold, the distribution of plants and animals, the laws and processes of life, a knowledge of mechanics, of manufacture of commodities—about these things no one should be wholly ignorant, but for many a general conception must suffice.

Then on the other side come the history of the human race, the rise of man, the growth of ideas, emotions, religious beliefs, the shaping of communities, the interplay of nations, the history, in fact, of civilisation—all this belongs to what may loosely be called the literary side. But to deal merely with scientific conceptions and laws, and not to teach how the spirit of man has developed, how he has organised human society, how he has slowly discovered and availed himself of scientific knowledge, is to leave out what is, perhaps, our main concern. What we have to do is not to leave our youthful citizens in a sort of bewildered solitude, just aware of the little circle in which they live, but to give them on one side a sense of what the natural world in which they live is like, as well as a notion of how humanity has developed its institutions and its principles.

The third aim of education is to train children in good moral and physical habits, to develop wholesome mental interests and robust health of body—the training of character in fact. But here the problem is a complicated one. If we only nurture the young in strength and health, and encourage them to believe that the world is a place to get all they can, to fortify themselves in wealth and comfort, we have not developed good citizens at all. They must learn what duty and service and self-sacrifice mean, and that a man's concern is not only himself. This can only be done by the cultivation of an imaginative sympathy, which can put itself in the place of another, and desire to share rather than to amass happiness. This can only be communicated by a perception of the beauty, the generosity, the heroism of human nature, its hopes and aims; and this I believe frankly cannot be attained by the knowledge of scientific laws, but only by human records and the noble flights of human imagination. A literary education is a feeble enough thing if it only deals with grammar and syntax, artifices of style, the jingle of rhythms and prosodies, the devices of ornament and cadence—and this was the fault of the classical education, that it so seldom broke through the outworks into the citadel itself. But the truer and more scientific view of literature is that it is the evoking of a real love of spiritual beauty, and that the masterpieces of literature are great, not because they conform to the rules of critics, but because they answer most nearly to the best and loftiest

visions of the human soul—that Homer and Shakespeare and Dante, let us say, are great because they best mirror man's greatness, and not because they afford most scope to the inquisitive pedantry of scholars. What, indeed, we have to fight against is pedantry, which is simply the fault of natures so onesided in their preference that they invest the smallest details of their study with a significance and an importance that violates all proportion. The literary pedant and the scientific pedant are alike mischievous, because they worship detail and disregard design.

The aims, then, of education are the fortification of health and character, the communication of a general conception of the world as it is, both socially and physically, and the discovery of aptitude and ability, so that the resources of the State may not be wasted or dissipated.

Our education, then, must be framed on these generous and elastic lines. What wasted time and energy, and dispelled all intellectual curiosity in the old classical curriculum, was the futile insistence on petty detail. Few boys ever struggled through the mass of trivial elements with which they were confronted. Exactly the same will be the fate of the strictly scientific education if we exchange one tyranny for another. When I was an Eton boy, forty years ago, science was just beginning to be taught in the school. I remember well a course on hydrostatics which will serve to illustrate my point. There was no apparatus available. Our teacher gave us a general view of the subject in two or three preliminary lectures, with a few very ill-drawn diagrams on a blackboard. Still, I remember that this was not without some interest. But our teacher was really a mathematical master, and as soon as possible we began to calculate the weight of columns of water—and thus continued for the remainder of the term, so that it became a baser sort of mathematics, and induced in my mind the conviction that hydraulics was the dreariest of subjects. I remember a scene which took place at one of these lectures. Our teacher had drawn upon the board a hydrostatic press with an object in it of which he diffidently said, "It might be a cheese; it might be a hat-box." A lively youth, who has since won some distinction in literature, said in a cheerful tone: "But what is the use, sir, of all this?" To which the bewildered instructor, poising his chalk in his fingers, said: "Use? Use? What's the use of you?"

On the other hand, when I was a boy of nine, my father, who was then headmaster of Wellington College, and had a great belief in the admixture of science with literature, arranged for some popular scientific lectures for the school, and took me in to one on elementary physiology, dealing with the digestive apparatus and the blood. It was illustrated with simple apparatus and lantern slides. I can only say that it awakened my curiosity to an extraordinary degree, and I have never forgotten what I then learned.

What I would deduce from these personal adventures is this—that to most boys, even a boy like myself, whose tastes even then were mainly literary, the general notions of science are extremely attractive and interesting, but that when they come to be exactly applied they suffer the same eclipse that the classics suffer by over-emphasis on grammar.

Now I am not to be supposed to be recommending that education should be a loose, vague stimulating process. I believe that toughness and exactness of mind must be relentlessly pursued. But the question is how and when. If it is the only thing aimed at from the beginning, the effect upon immature minds is simply to obliterate interest by means of drudgery. The poisonous part of the classics, taught as if everyone was to be a classical specialist, was to hang the veil of grammar and syntax between us and literature. The mind of boyhood must be for ever wooed to learning. The boy is capable of taking an immense amount of trouble if only he can be persuaded that he is not doing work; but to extinguish his fancy, his imagination, and his curiosity is a fatal mistake. What I therefore plead for is that up to the age of fifteen, or thereabouts, the boy's interest, curiosity, liveliness, emotion, sense of beauty, sense of amusement, should be firmly kept in view. It must not be all discipline. The use of mathematics, the training in a modern language, the writing of clear and correct English, the orderly arrangement of thought, are all disciplinary; but unless there is interest and animation, all this is purely mechanical. Many a boy has a pride in authorship; the difficulty is that he has no stores to draw upon. Here science and literature can be easily intermingled, if boys can be taught to write clear accounts of experiments which they have seen. The old literary exercises were dreary because they had nothing to do with the boy's own experience. The same must be done with literature. A part of English teaching ought to be simply to show the boys how to read the great books. We used, in my Eton days, to be set a play of Shakespeare for a holiday task.

What did we do? We read the historical introduction, and we got up the notes—about such things as "kerns and gallowglasses"—we did not read the play at all, except that we learned some twenty lines by heart because we were generally asked to quote any passage we had admired. In dealing with older literature there are three sides to consider—imagination, expression, erudition. The result of our teaching was to neglect the first, to dally with the second, and to converge upon the third.

If by the age of about fifteen or sixteen you have assured a boy's interest in general ideas or science and literature, given him some sense of history, by which I mean European history of a biographical and social rather than of a diplomatic or military kind, taught him to read and write simple French, to read and write English, to calculate quickly and correctly, you have done a great deal. It is very difficult to say exactly what we mean by a well-educated boy of eighteen; but if a boy of that age can read an interesting book on some subject of general current interest with something of a critical spirit, and is not wholly at the mercy of a specious and attractive presentment; and if, moreover, in reading a newspaper he does not confine himself wholly to the athletic column, but wishes to know more or less what is going on in the world—well, I for one should be ready to admit that he was a well-educated boy.

There is a delightful story told of Hookham Frere, who was the lifelong friend of the great Canning. "I was walking with Canning," Frere said, "over Wimbledon Common, and we came to a little pool into which Canning gazed with a lively curiosity. 'Frere,' said he, 'what are all those funny little black creatures crowded together and swimming about so busily?' 'Tadpoles, of course,' said I. 'These are tadpoles, are they?' said Canning. 'I have heard the name, but never saw them before. And, pray, what *are* tadpoles?' 'Well,' said I, 'they *are* tadpoles, but they *will* soon be frogs.' 'But these are not frogs,' said Canning, 'nor in the least like them; they are a sort of little fishes.' 'Don't you really know,' I said, 'that tadpoles are the young of frogs?' 'No,' said Canning, 'I never heard of such a thing; are you sure? They are the oddest little things I ever saw.'"

"Now," said Hookham Frere to his auditor, "don't you go and tell that story to the first fool you meet: Canning did not know that tadpoles turned into frogs, but he could rule a great nation, and he would not have ruled it any better or any worse if he had known. There are hundreds of things just as true and real which none of us know. It wasn't his business to know about tadpoles; it was his business to know about politics and foreign affairs, and to be a good judge of men."

This story goes side by side in my mind with a story of the poet Clough. A sort of consternation had been caused among a party of Dons by a very active politician who had admitted that he had never heard, so far as he knew, of the battle of Marathon. Someone said to Clough afterwards, "Is not that simply incredible?" "I don't know," said Clough. "I don't see what difference it made to him not knowing about it. Of course, it has made a great difference to us all that the battle of Marathon happened, and that the West held back the East. But no doubt many more important things happened in pre-historic times about which we do not know. I don't see what difference the mere knowledge makes."

There is much truth in that. We are much too disposed to think that knowledge in itself is valuable. It is valuable precisely in so far as it inspires and animates and trains the mind. The mere knowledge of facts is very unimportant. The expert must know the facts and processes of his subject, of course; but apart from expert knowledge, no knowledge is valuable which does not mean the kindling of interest and faculty. The fact which one cannot forget is the significant fact, not the fact which it seems easy to confuse or impossible to remember. In my own mind, certain facts are self-evident almost, while others melt like snow in a thaw; but I do not, therefore, hold that the facts which I remember are important, and that the facts which I forget are unimportant—it is all a question of the range and quality of minds, and the extent to which facts modify the work they are doing. I cannot help feeling that in the present push for science as an educational subject a certain confusion exists between the practical utility of science and its value as an educational subject. Elementary and general acquaintance with concrete phenomena and technical processes has no practical utility at all; it is the expert who is useful, the highly-trained specialist. A thing which is practically useful has not necessarily any educational value. What we want to discover is a subject or a set of subjects which quicken intelligence and observation and sympathy and accuracy, which extend the imaginative horizon, which make a man accept his duty and his place in the State,

not as a matter of unpleasant necessity, but as a matter of active and eager concern. I do not believe myself that any one subject can do this. If literature, as it has been taught, has failed to exert this influence, I see no reason to believe that science *per se* will do it either. While we abominate the aggressive and mediæval theories of domination which have plunged Europe into strife, it is the tendency of, at all events, a section of our community to point to Germany as a country which has contrived to produce an extraordinary average of efficiency, a formidable unanimity of aim. Yet, if we look at German secondary education, we find that science is actually taught for fewer hours in their schools than in our own. That has been established by the new Committee which is examining the question of scientific education. It is certain, I believe, that if scientific education has not had a fair chance, it is not for want of time or of apparatus—it is much more a question of method, and still more of teachers. This is really where our difficulty lies. We do not believe sufficiently in education to pay our teachers properly or to make it a career for the best men. The personality of the teacher is the root of the whole matter. What we want is men not only of clear intellect, but men with a touch of inspiration, with a living interest in the beauty and nobility of the subjects they teach. There are many dormant seeds of interest and faculty in boys' minds which can only be quickened to life by something ardent and fructifying in the mind of the teacher. A good teacher is hardly cumbered by a bad curriculum, a bad teacher is hardly assisted by the best curriculum. It may be said that it ought not to be a question of money, but you cannot expect any but the real enthusiasts to embrace a profession which hampers them at every turn with straitened resources and pecuniary anxieties. A man who wishes to marry and bring up his children liberally and intelligently will go where he can find the means of doing this. You may depend upon it that we shall do nothing in education by a mere juggling with curricula; we shall only do it by securing good and enthusiastic teachers. The imitative faculty of boys is great; and if they see a teacher who really derives animation and joy from his subject, they will wish to acquire the same happiness. Education is not a scientific process; it is a contact of living minds. I remember once examining a number of educational experts on the question of the curriculum. Each of them had some one subject which he declared had solved the question of discipline and drudgery by evoking a natural interest in the pupils. It gradually dawned upon me that each was selecting the particular subject in which he was personally interested; and I perceived that what had carried the day in each case was not educational technique but personal enthusiasm.

Let me, then, very briefly summarise my conclusions. What we want is a simple and elastic curriculum which shall cater for individual taste and aptitude, and correspond in a general way with human faculties and interests. Intellectual discipline—by which I mean that most valuable power of mastering a subject whether you are interested in it or not—can be attained to a certain extent by the uncongenial subjects whatever they may be. But I do not believe in intellectual progress being possible without intellectual interest. The general aim of this curriculum should be to give the pupils some conception of the world as it is; and in this science, literature, art, music, history, geography, mathematics, handicraft, language and religion must each have a part. Imagination, logic, clearness, observation, interest—these are qualities at which we should aim. Then, when special aptitude is discerned, in the later stages, a certain specialisation may begin. What really happened in classical education was that, under the guise of a pretended width of culture, all minds alike were forced into a premature classical specialisation, and this mistake we must not repeat. And, lastly, we must make the profession of teaching remunerative and dignified—that is the most important point of all; and unless we can do this we may shift our curriculum for all eternity without ever emerging out of a ramshackle sort of drudgery which will continue to hang like a dreary veil between the ingenuous child and the glowing interests of the great world in which he has to live and play his part.

DISCUSSION.

THE CHAIRMAN (the Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S.), in opening the discussion, said he had seldom listened to a discourse of forty minutes which contained more truth put more brightly and agreeably, and the only difficulty he had in commenting upon it was that it raised so many interesting lines of thought. He would, therefore, confine his attention to some of the most important propositions that had been laid down, and the conclusions most suitable to the present time. In the first place, the author had said with perfect truth, although the obvious

fact was often forgotten, that there was in most minds a hopeless confusion between the practical utility of a subject and its educational knowledge. The two had literally nothing to do with each other. The things which were of most use might be the things which an individual could not learn or understand. For instance, nothing touched an individual, next to his conscience, more than his health; but if he undertook studies in physiology and pathology, with a view to making himself capable of dealing with his own health, he did the very worst possible thing for it—he would always be in the doctor's hands. In the second place, the author had stated that literary subjects, and, above all, studies of the ancient classics, had been ruined in the minds of most boys by the undue insistence upon those grammatical minutiæ which might be interesting to the teacher, and which were, in a certain sense, the foundation of a thorough knowledge of the languages, but many of which were beyond the intelligence of the ordinary boy, and of little or no value for the appreciation of good literature. Long treatises had been written upon the particular use of μὴ οὐ and οὐ μή, but it was perfectly possible to appreciate Greek literature with the scantiest knowledge of both of them. That was a thing which it was earnestly to be hoped might be reformed, and it would be reformed if the new race of teachers existed for whom the author sighed. In the third place, the author said with great truth that it was necessary to pay the teachers better. The teacher was the school; the curriculum was the teacher. The good teacher made every curriculm interesting, and it was impossible to expect to have the choice intellects required for the work of teaching—especially the higher kind of teaching—without paying them better, particularly in view of the manner in which all prices had risen during the last twenty years. The country ought to be prepared to go further in that respect, feeling sure that in no direction could it make an expenditure that would be more truly remunerative. In the fourth place, the key to the question in regard to classics was that classics were an instrument for the training and developing of the mind and thought of the best pupils. Classics would be thrown away in their highest literary quality upon the majority of pupils. The problem was how so to order the arrangements of the schools and universities that it would be made certain that the classics would continue to be taught to, and studied by, the best students—whether that percentage be 20, 30 or more—who were fitted to appreciate the true value of classical literature, to make it a part of their minds, and to make it interpretative to them of human nature and of history. That was the real object of classics—to appreciate the ancient world, to get a grasp of the worth which was in those ancient races, and which was precious because of that, and without which no history could be comprehended. But how was that to be done, and how were the classics to be kept in the universities and in the higher branches of schools, with due regard to those who would not reach that point in classical study? That was the kernel of the present difficulty. They did not want to impose classical study on everyone, and yet they wanted to have the opportunity of discovering who it was that possessed the qualities which would enable him to prosecute it with real advantage to himself and real benefit to the whole community. One of the greatest difficulties which the teacher experienced at present was the passion of boys for the athletic column, to which the author had referred. He believed that no small proportion of the difficulties which teachers felt was owing to the extravagant fashion which boys had contracted, not for athletic sports—the sports themselves were admirable, and it was impossible to have too much sport and physical training for the boys—but the passion for reading and thinking about them. That was a feature which was comparatively new. When he was a boy at school there were no athletics—he wished there had been—but he was almost glad that there were none, because there was then no athletic column and no such thing as a sporting journal. There was no boy in his school of 700 boys that ever read anything about any athletic sport whatever. That was a state of things which it would be impossible to regain; *i.e.* he did not believe it would be possible to have athletic sports in a school, which were eminently desirable, without having that passion, but he thought the passion for reading about them had reached extravagant proportions. The great aim of education was to create the habit of observation, of intellectual curiosity, of thinking, and of reflecting upon what one saw. That was the real end of education in all its branches, whether it be science, literature or history. What teachers wanted to do was to make knowledge delightful to the mind. It was not knowledge that was important, but the love of knowledge. An education which instilled a real love of knowledge and the desire to make every step in knowledge a step to something else, and the basis for thought and reflection in the mind of the pupil, had attained its object. And the best education was that which did it best.

Dr. G. Armitage Smith (Principal of Birkbeck College, London) said he fully endorsed all the opinions that had been expressed upon the general problem of education. There were two sides of education—arts and science—and he had often thought that those who specialised more particularly on one of them were not as much in real contact with the subject as was desirable. The crux of the whole matter, as the author had clearly pointed out, was that training either in science or in arts up to some point was necessary to get an educated man, a man who had learned to think. If the paper were widely circulated he thought it would solve a great many difficulties that were in men's minds. During

the last year or two he had read many educational papers with the object of endeavouring to ascertain what were the correct views upon education, and he was completely perplexed; some said that science was the only thing, while others said it was arts. The author had shown that it was neither science nor arts alone, but the theory which was involved in both that was necessary—the training of the mind, the love for knowledge, and the power of expressing it.

SIR WILLIAM A. TILDEN, D.Sc., F.R.S., said that as a teacher of science for fifty years he had always held in due respect the subjects which were claimed to possess such magical powers by the representatives of literature, and he therefore felt much gratified to find that the author had shown a kind of liberality of view without which it would be impossible to get to the end of the dreadful controversy which existed. The conflict between literature and science had been going on from as far back as he could remember, and he had always thought that it was a most deplorable state of affairs. He thought it would be found, however, that it was only the extreme partisans on either side who held the extreme views. Unfortunately, some literary people, especially those who pursued the study of the classical languages, were particularly obdurate in their attitude; on the other hand, it must be admitted that some of his scientific friends went further than he personally would like to do in pressing the claims of science as a department of learning or as an educational subject on the teaching community. He thought the paper would have a very valuable effect in helping to modify the extreme views which were held by the partisans on both sides. He had felt for many years past that the statement made by the Chairman was perfectly true, that the study of the classical languages with a view to claiming an acquaintance with classical literature applied only to the best of the boys. Personally, he would like to go a step further and divide the boys into four classes. In the first place, there were the superior, intelligent boys, who were drawn on the one side to literary subjects; in the second place, there were the superior, highly-intelligent boys who were drawn to the other side, the observation of nature and the study of experimental science; in the third place, there was the mass of good boys, generally speaking, who received good reports from the schoolmaster and who made excellent citizens, but who were not brilliant: they would go whichever way their parents or their schoolmaster invited them to go. But there was a fourth class which had never been properly provided for, and he could not help thinking that much educational energy had been wasted in the past in endeavouring to make the lame ducks run. There was a certain class of boys and girls in whose minds it was impossible to arouse any particular kind of interest, no matter what subject was presented to them. Those students, in his view, should not be allowed to cumber the classes of the schools; they should be promptly turned out at a certain age, say, sixteen or something of that kind, and made to pursue some other useful employment, which would be much more satisfactory to themselves and more valuable to the community. That question ought to be faced at the present time, when things in general were being treated in a serious spirit, and he hoped it would receive more serious consideration than had been the case in the past. He noticed with much interest, a few months ago, the scheme put forward by Dr. Lyttelton, who had just left Eton, in which he provided a class for boys in which neither Latin nor Greek was taught; everything was to be English, with a little mathematics. That was the first attempt that had been made to deal, by a definite system, with the class of what it was impossible to avoid calling stupid boys. He congratulated the author on having made a move which, from the authoritative position he held, would have a good effect in modifying the extreme views of people on both sides.

DR. R. MULLINEUX WALMSLEY (Principal of Northampton Institute, London) thought the present crisis in the educational world was of no less importance than the crisis in the political world, and that the views enunciated in the paper would lead along the right path to a solution. He did not propose to speak from the scientific side, because, like the author, he thought there should be no antagonism between literature and science when the subject of education was being discussed. It was not what an individual learned that was the important thing, but how it was taught, how knowledge was acquired, and the influence of the teacher. One of the statements in the paper which appealed to him most deeply was the remark that, in order that our educational system might enter upon a new phase, it was necessary to attract into it the best intellects of the country, and that to do that the prizes in the educational world must bear some relation to the prizes in other walks of life. In that way the ideal teacher that the author indicated would be obtained, namely, *the* man. It was the man in the highest sense of the word that was required for educational work. Nothing would so influence the coming generation as the personality of the teachers in the schools, and unless that personality was obtained curricula, whether scientific or classical, were of no consequence whatever. He differed from Sir William Tilden's nterpretation of the Chairman's remark, that only the best boys in the school would arrive at the highest literary attainments taught in the school. Personally, he interpreted the Chairman to mean that only the best boys with the literary instinct would get that far, and that there were best boys in other directions. The best boys were not to be picked out because of their interest and their acquirements in a single side; it was necessary

to have the others as well. He had very much sympathy with the "submerged tenth"—he was afraid it was more than a tenth—to which Sir William Tilden had referred; and he had publicly stated on a previous occasion that there were certain boys and girls upon whom the money of their parents, the time of their teachers, and the accommodation of the class-rooms should not be wasted after they had acquired the three R's. They should be put to something else. It was perhaps rather hard on the boys, but those who came in contact with large numbers of them knew that there were in the schools boys who not only wasted the time of their teachers, but also kept back the classes. He was afraid that the paper had not given a solution to that problem, which he commended to the attention of all educationalists, because if that part of the problem was neglected the highest education in the schools would be impeded by that residuum.

Professor A. C. Seward, F.R.S. (Master of Downing College, Cambridge), thought, as the author truly said, that one of the first aims in education was to discover the aptitude of the student, and that often seemed to him one of the strongest arguments in favour of the suggestion that science should be taught to every boy in a school. Many boys who had not had the opportunity at school of learning any of the natural sciences had, on that account, largely wasted their time, and they had perhaps been classed as the "submerged tenth." There were a good many boys who for years during their school life appeared to have no particular aptitude for the ordinary school work, and yet in later life, after they had gone to the university perhaps, they suddenly discovered something in which they were really interested, and that was not infrequently some science subject. It was not because he desired everyone to be a scientific person that he advocated the teaching of science to all the boys in the school, but largely because by doing so there was more chance of discovering boys who had an aptitude for that particular branch of learning. It was often overlooked that success depended very largely indeed upon the personality of the teacher. He had often felt that the great aim of a teacher should be to make his pupils interested, a point that was frequently overlooked. A lecturer often worried as to whether he had sufficient facts for a lecture, but he frequently did not pay enough attention to the question of whether he was going to place the subject before the students in such a way that it would be interesting and real to them. If boys could be made interested in a subject they would do almost anything. The author had touched upon the question of science, as contrasted with literature or classical education, from the point of view of the effect upon the training of the imagination. In one or two of the statements the author had made he did not think sufficient credit had been given to science, more especially biological science, for the influence it had, if properly taught, on the spiritual side of a boy's life. The author spoke of science as being the study of material environment and as being to a certain extent rather materialistic, whereas other subjects tended to develop the other side of a boy's character. He felt a great deal of sympathy with the remark of a character in one of Meredith's books who said, "Men of science, my Cassandra, are always the humanest." Some of the most human people he had known were people who had been naturalists—not necessarily people who had the most minute or intimate acquaintance with any particular science, but people who had been brought up from their youth to love nature, who had been taught science at school, and who had gone on in after-life teaching themselves. He did not know any subject which, if properly handled and placed before students in the right light, was more likely to develop the good side of their nature. Some people held the idea that if a person knew anything about the structure of organisms, of a flower or an animal, they lost their æsthetic pleasure in it, but he was absolutely certain that was not the case. He did not mean for a moment to suggest that science could in any sense replace what a literary education could give, because he felt that anyone who was brought up on a scientific education, without due attention having been paid to a love of good literature, was only half developed. He thought the tendency was more and more noticeable at the present time not to push one subject, science or classics, as they were generally called, at the expense of the other, but that, as the author said, due attention should be given to both. He was very pleased the author had quoted the story about Canning, because it expressed the opinion he had often held himself, namely, that one came across so many people who professed to be ashamed of not knowing certain things. The late Bishop of London made a remark which it seemed to him was exceedingly true in that connection, namely, "Never be ashamed of not knowing, but be dreadfully ashamed of not wanting to know."

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Benson for his interesting paper.

Mr. A. C. Benson, in reply, after thanking the Chairman and the other speakers for the very kind way in which they had received the paper, said he desired to emphasise, in order that there should be no misunderstanding, the point which one speaker had brought out very clearly, that the whole object of the paper was that there should be no antagonism between the two sides. He agreed with Dr. Seward that science should be taught to all, because he thought there was a certain stage in the development of the human mind when concrete observation was alive, before the reflective powers came into full swing, when a child was inclined

to pull everything to pieces and ask questions, which parents found it so impossible to answer, partly because they did not know and partly because the questions themselves were unanswerable. Quite in the early stages, and up to the time when the roots divided, science should be taught to everybody, and an attempt should be made to make the mind more or less familiar with the whole range. When he was a schoolmaster at Eton he tried an experiment which seemed to him to be fruitful of great possibilities if it could have been further developed. He bought one day the entire stock of a newsvendor of a morning paper, gave a copy of the paper to each boy, and lectured on the paper as a whole—the weather reports, markets, and everything else. He knew enough of the subjects to teach the boys that the views of the world were making themselves heard through the paper, and showed them that, although it might be difficult to believe it, there were distinguished and intelligent people who, immediately they received the paper, hurriedly tore it open and looked first at the item that interested them, however dull and unintelligible it might appear to the boys. He wanted them to appreciate that the paper represented the life of the world; he wanted the growing boy to get some conception of the world, not only as it was seen and viewed, but as it was heard of in books. Dr. Seward had alluded to the imaginative value of science. Tennyson, as a boy, was very much devoted to astronomy, and when one of his brothers complained that he had been invited to tea at the neighbouring vicarage and that he felt shy, Tennyson said: "Why not try and think of the star clusters?" The brother tried to do so, but pronounced it a most colossal failure. When he was confronted with the circle of faces round the tea-table at the vicarage, no amount of turning the mind on to star clusters and constellations was of the slightest help; it only made him feel more shy than before. Lord Bryce had inquired whether classics were to disappear in the scheme that had been suggested. They would not, according to his theory. As a matter of fact, Latin was probably certain to hold its own for the present, although personally he did not think it was a very good subject to keep. It was supposed to be a good mental training, and to be the basis of many other tongues; but if the object of education was to teach the other tongues, why not teach them instead of the basis? The real difficulty about Latin was that Latin prose which was suitable for amateur minds was practically non-existent, whereas, so far as Greek was concerned, the "Odyssey" had been taught to many generations of boys, and he had seldom known any who had not been touched to a certain extent by the finest and greatest story in the world. The "Cyropædeia" was also an excellent book from which to teach Greek to boys. There was nothing like that in Latin at all. Cicero and Cæsar were the mediums generally employed, and he personally felt that Cicero was singularly calculated to disgust the intellectual processes of the youthful mind. Cæsar was a hard, compressed, rather rhetorical commentary on the most minute military operations; one moved slowly through a kind of dim light without any idea of what it was all about, reminding one of the hymn—

". . I do not ask to see
The distant scene; one step enough for me."

Lord Bryce suggested to him that Cornelius Nepos might be taught, and that was a possibility, but he thought there was a singular tenuity in the lives of Nepos. He was very grateful to his lordship for emphasising so strongly the object of education—the habit of observation, intellectual curiosity, reflecting upon what one saw, and making knowledge delightful to the mind. That was what they were aiming at, and that was what he believed an education based, to a certain extent, on the principles he had attempted to enunciate might do—*i.e.* an education with a broad sweep, not neglecting anything, with no antagonism, but merely attempting to acquaint the minds of the boys whom they wished to educate with the world as it lay about them, the history of the human spirit, and some outlook upon the future which would make the human race brighter and better instead of more complicated and dim.

THE HURTER AND DRIFFIELD MEMORIAL FUND.

The Royal Photographic Society have appointed a committee to collect subscriptions for a memorial to Messrs. Hurter and Driffield, whose researches did so much to advance both the science and practice of photography. As their work is little known to the very numerous public who now practise photography, some account of it may be interesting. Dr. F. Hurter (who was of Swiss nationality, and was born at Schaffhausen) died in 1898 and V. C. Driffield in 1915.

Hurter and Driffield studied for many years with great thoroughness the quantitative relationships between causes and effects in the various processes employed in the making of a photographic negative. They showed by measurement with simple photometric apparatus that the amounts of silver reduced on development of a sufficiently exposed plate are proportional over a reasonable range to the logarithms of the exposure products (intensity × time), and from this deduced their well-known methods of determining the speed of photographic plates.

Much valuable work was also done on the influence of the composition and time of action of developers, and the results obtained by them have been of very great value to photography. Without the powers of quantitative examination and exact definition of the qualities of plates put in the hands of the manufacturers by Hurter and Driffield, the English dry plate

manufacture would never have attained the excellent position it holds to-day.

The conclusions Hurter and Driffield drew from their researches have, as a whole, well stood the test of later and more critical examination, and the stimulus they gave to the scientific study of photographic problems has resulted in the growth of a new branch of scientific inquiry for which many laboratories are specially equipped, and which no manufacturer of photographic dry plates can now afford to neglect.

The committee ask for funds to enable them to carry out the following objects :—

1. The endowment of a Hurter and Driffield Memorial Lecture.
2. The provision of suitable accommodation for the apparatus and manuscripts bequeathed to the Society by the late Mr. Driffield ; and
3. The publication of a book containing the collected papers of Hurter and Driffield.

The hon. treasurer of the fund is W. B. Ferguson, Esq., K.C., 48, Compayne Gardens, South Hampstead, N.W.

NOTES ON BOOKS.

DISCOVERY ; OR, THE SPIRIT AND SERVICE OF SCIENCE. By R. A. Gregory. Macmillan & Co. 1916.

Mr. Gregory states that his object is "to promote a more sympathetic attitude towards those who are engaged in the pursuit of scientific truth" and "to remove the widespread misconception which prevails as to the meaning and influence of science." Surely, however, the case is not quite so bad as all that ? Scientific men have no great cause to grumble at the way they are treated nowadays, and the prevalent misconception about the powers of science is probably to overrate them.

There is, however, no doubt that scientific men, as such—men who devote themselves to pure science—do not get the same amount of public distinction, or acquire the same amount of wealth, as men who successfully devote themselves to law, medicine, the church, politics, or other means of acquiring profit or renown. There are but a small proportion of scientific peers, Privy Councillors or baronets, and even the initials tacked to the names of "scientists" indicate more often association with societies and universities than with knightly orders. Even in America the scientific millionaire is as yet unknown. But, after all, men make money by supplying their fellow-creatures with services they desire. They cure their diseases, they prosecute their law cases (either protecting them from nefarious attacks or averting the consequences of nefarious performances), they write them the sort of books or paint them the sort of pictures they prefer. You may render your fellow-men the greatest services you like, but if they are not the services they require you will get neither cash nor credit. So must it be with men of science. They must submit to actualities. If they want money, and the various distinctions which follow on its possession, they must devote their talents to practical purposes. If they prefer to devote them to the advancement of human knowledge, they must be satisfied, like many of the greatest students, authors, poets, painters and philosophers, to work for no pay and limited appreciation.

It really, therefore, may be doubted whether there is a very urgent need for an appeal on behalf of down-trodden and neglected science. But if such an appeal is to be made, there could be nobody better qualified to make it than the assistant-editor of *Nature*. For many years he has had to deal with every branch of scientific knowledge and to record every advance made in it. And he has made good use of his opportunities, for he has collected together a very considerable number of illustrations, mainly historical, anecdotes, records, and examples, all interesting, and nearly all, so far as a somewhat cursory inspection justifies opinion, quite accurate. His evidence is unimpeachable, but his conclusions are very much open to argument. In the familiar words of the "Evidences," it may be true enough that many have "passed their lives in labours, dangers, and sufferings . . . in attestation of the accounts which they delivered," but it is equally true that many others have turned their scientific knowledge to very practical account, and have acquired by its wise application large and well-deserved emolument. Nobody would go about saying that scientific research had conferred no benefits on humanity ; but with all her beneficent influence it is not to be denied that science, like religion, is responsible for an infinity of human pain and anguish. The past two and a half years provide evidence enough of that.

Assuredly also nobody would want to stop scientific progress because among its results are included aeroplanes, submarines, and high explosives as well as anæsthetics and radiography. But unreasonable laudation rouses antipathetic depreciation, and if we are to have a record of the "spirit and service of science" the case ought to be fairly stated. But perhaps we ought to remember that Mr. Gregory does not pose as a historian or as a judge, but as an advocate, and we must not expect judicial impartiality in counsel's speech for the prosecution. The pity of it is that nobody is likely to accept a brief for the defence, so we shall never hear the other side.

At all events the author has produced a book of an original and attractive character. It contains a great deal of interesting matter, and students of the history of science may read it with much profit and advantage.

THE CANNING OF FRUITS AND VEGETABLES. By Justo P. Zavalla, M.S. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 10*s.* 6*d.* net.

In the earliest attempts to preserve fruit, vegetables and meat, it would appear that glass was universally employed for the containing vessels, but in 1825 Thomas Kensett secured a patent for the use of tin cans, and he at once began to make them in his factory. Since that time the use of cans has increased to such an extent that now, as Mr. T. F. Hunt says in the introduction to this volume, "human beings may be traced in almost any part of the globe through the cans which they leave behind them."

The art of canning fruits has probably approached nearer to perfection in California than in any other country. Mr. Zavalla, the author of this book, is a graduate of the College of Agriculture of the University of California; he has himself contributed considerably to the study of the preservation of fruits and vegetables, and in this work he embodies a vast amount of scientific and practical information on the subject.

The volume is divided into four parts. The first deals with fruit canning, and describes the methods of purchasing the fruit, of receiving it in the factory, of selecting and preparing it, the various ways of peeling and slicing it, and grading it according to quality. The canning department is next dealt with, the preparation and grading of the syrup, exhausting, processing and cooling, and finally the machinery for canning and can-making.

Part II. similarly deals with the canning of vegetables, especially asparagus, beans, cabbages, cauliflowers, corn, peas, and tomatoes.

In Part III. micro-organisms and spoilage are treated. The methods for the bacteriological and microscopical examination of spoiled canned foods, and the apparatus required therefor are fully described, and there are various valuable sections on moulds and yeasts. The subject of the fourth part is the making of sanitary cans.

The book is illustrated by numerous diagrams, both of machinery and of putrefactive micro-organisms, and provides a very excellent account of a great and growing industry.

GENERAL NOTES.

MARTELL SCHOLARSHIP IN NAVAL ARCHITECTURE.—A scholarship, designated the "Martell Scholarship in Naval Architecture," will be offered for competition by the Council of the Institution of Naval Architects. The scholarship is of the annual value of £100, and, subject to the conditions named below, is tenable for three years: (1) Candidates for the scholarship must forward a written application to the Secretary of the Institution of Naval Architects, 5, Adelphi Terrace, London, W.C., to reach him not later than January 15th, 1917: (2) Candidates are not to be less than eighteen nor more than twenty-one years of age on March 1st, 1917, and must at that date have been continuously employed for at least two years upon naval architecture or marine engineering; (3) the scholarship will be awarded in connection with the competitive examinations for scholarships, studentships, etc., to be held by the Board of Education in May and June, 1917, in the following subjects:—Naval architecture; pure mathematics; applied mechanics (materials and structures); either (*a*) applied mechanics (machines and hydraulics), or (*b*) heat engines.

IRON INDUSTRY AT CAEN.—The iron mines and blast furnaces of Caen (Normandy), after having been in a languishing condition for many years, are once again most flourishing. In 1900, during the period of greatest stagnation, the production of the local mines reached only about 142,000 metric tons of iron ore, as compared with 12,000,000 metric tons produced by Lorraine, though the Normandy ore is richer than the other. In 1909, according to a report by H.M. Consul-General at Havre, the German Thyssen interests obtained a foothold in the industry, and thenceforward considerable German and Dutch capital was invested therein. On June 1st, 1914, the number of mining concessions was twenty-one, of which twelve were being fully worked, producing annually 750,000 metric tons of iron ore. New plant of the most modern and powerful kind is being installed, and the railway authorities are doing everything in their power to assist the development of the industry. The output of iron ore in this district has now reached over 1,000,000 metric tons annually.

TOBACCO IN NEW ZEALAND.—Some particulars are given by H.M. Trade Commissioner in New Zealand of the cultivation and manufacture of tobacco in New Zealand by a syndicate which possesses a tobacco plantation at Clive Grange. Since operations were begun three years ago the company has raised three crops, partly under most unfavourable weather conditions, last season's crop having had practically no rain. The nine months of drought experienced in that year had no adverse effect on the tobacco crop, and it did not suffer from blight or pest. The New Zealand grown leaf is said to contain hardly 1½ per cent. of nicotine, which compares favourably with American-grown tobacco. Among the classes of tobacco produced by the company are plug, flake, long cut, bird's eye, and shag. British firms interested may obtain further particulars on application to the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, London, E.C.

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—December 22, 1916.

Journal of the Royal Society of Arts.

No. 3,345. VOL. LXV.

FRIDAY, DECEMBER 29, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 3rd, 3 p.m. (Juvenile Lecture.) Mr. ALAN A. CAMPBELL SWINTON, F.R.S., "Electricity and its Applications."

The lecture will be fully illustrated with numerous experiments.

Special tickets are required for the Juvenile Lectures, and no person can be admitted without one. A few tickets are still left, and these will be issued to Fellows who apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, December 14th, 1916. The RIGHT HON. LORD EMMOTT, G.C.M.G., took the chair at the commencement of the proceedings.

THE CHAIRMAN, in introducing Professor Todd, asked to be allowed to depart from the usual custom and to say one or two words himself in advance. He regretted that other engagements, new since the time when he promised to preside, made it necessary for him to leave the meeting at once. He would, therefore, be unable to have the pleasure of listening to what he knew would be an extremely interesting paper, and he apologised to Professor Todd and to his audience for running away as he would have to do. Perhaps, however, they would permit him in the circumstances to say one or two words about the subject of the paper. He entirely agreed with the author that India was probably the only country in the world to which we could look for a great and rapid increase in the production of cotton such as was essential for the industries of the world. From the Lancashire point of view he might add that unless the quality of cotton coming from India could be enormously improved, the relief to the general situation which an increase of the crop in India would bring about would not accrue, at any rate, principally to Lancashire. To put it in an unscientific way, cotton seemed to him to be one of those commodities which took its permanent character rather from the soil and climate in which it was produced than from the seed from which it was originally grown. Of course, it was the business of men to overcome difficulties of that kind, and it was their business from every point of view to do whatever was possible to improve the quality of cotton grown in India. Putting it generally, unless we got cotton an inch or over in staple, with good, even running, year after year, it would not bring relief to the industries of Lancashire, whatever it might do to other parts of the world. The question was really of vital importance from the point of view of the industries of this country and of the Empire at large, and there was no question more deserving of careful and intelligent study and experiment. There was no one more capable than Professor Todd of speaking on this subject, for he was at present Professor of Economics at University College, Nottingham, and had been, previously, Lecturer in the Khedivial School of Law at Cairo, and last winter Special Lecturer on Economics in the Punjab University at Lahore. Therefore, he had had special experience of the matter with which he was going to deal.

[With a further apology for having to leave the meeting Lord Emmott then withdrew.]

SIR WILLIAM DUKE, K.C.S.I., K.C.I.E., then took the chair, and called upon Professor Todd to read his paper.

The paper read was—

THE WORLD'S COTTON SUPPLY AND INDIA'S SHARE IN IT.

By John Aiton Todd, B.L.,
Professor of Economics, University College, Nottingham.

The question of the world's cotton supply has again become extremely acute. On November 20th last the spot price of American Middling in Liverpool touched 12·59*d.* per lb. Less than twenty years ago the price was under 3*d.* per lb.; before the war it was over 7*d.*, while just two years ago it touched 4·25*d.* The present price is the highest recorded since 1869, when the cotton world was still suffering from the aftermath of the famine due to the blockade of the Southern ports during the American Civil War. The present position is, however, markedly different from that of the sixties. The high prices then prevailing were due to an artificial scarcity caused by the difficulty of getting cotton through the blockade. To-day's high prices are the result of natural and economic causes, which may quite well be repeated if the conditions of supply are allowed to remain as at present, and the question of how these conditions are to be improved is not merely of world-wide general interest, but also of special interest to the British Empire and particularly to India.

To make the present position clear, it is necessary in the first place to outline the essential facts which have given rise to it. These are briefly as follows:—

1. The world's demand for cotton has been increasing rapidly for the last fifteen or twenty years, and though the world's crops have also been increasing (see Table A in the Appendix) the actual consumption during recent years has only been limited by the supply. During the ten years before the war the year's consumption was actually in excess of the world's supply in five out of the ten. This is clearly brought out in Table B, which shows the world's commercial crops and mill consumption during these ten years, while it also brings out the very close relation between each year's excess or deficiency of supply and the world's prices of cotton during the corresponding season. It is, unfortunately, impossible to carry these figures on through the years since the war; but similar figures are given for the American crop alone which bring out a corresponding result since 1914.

2. The cost of production of cotton, especially in America, which still dominates the world's supply, has been increasing rapidly during recent years. In 1913 the writer, in the course of a tour which covered practically the whole of the American Cotton Belt, went very carefully into this question, and came to the conclusion that, unless the price of Middling American in New Orleans is round about 12 cents per lb.,* the field price of cotton is not sufficient to remunerate adequately the average planter in Texas, especially the white planters, who are more numerous there than in any other part of the Belt. The Texas crop, which in 1912 almost touched 5,000,000 bales, is about one-third of the whole American crop and one-fifth of the whole world's supply, and during the years 1903–13 Texas alone made 53 per cent. of the total increase in the acreage under cotton in America. The Texas crop is, therefore, indispensable to the cotton world, and the cost of production in Texas, which is admittedly higher than in any other part of the Cotton Belt (except perhaps the small areas in Arizona and California, where a superior quality of cotton is grown), must be covered by the world's price.

3. The slump of cotton prices in the autumn of 1914, due to the war, hit the growers very hard. Cotton sold in the districts at as low as 6 cents, and would probably have gone even lower but for the unexpected holding power which the planters as a whole displayed. Their financial position, aided by the improved banking system of the Federal Reserve Banks, proved much better than was commonly expected. At the same time, the difficulty of finding storage accommodation for a material proportion of such a record-breaking crop proved less insurmountable than was thought likely. The result was that prices remained relatively high, considering the huge crop (estimated at 17,000,000 bales actual, though only about 15,000,000 came into sight during the season) and the hopeless slump in the demand which marked the first few months of the war. When it is remembered that in 1911–12, with a crop of only 16,043,000 bales, Liverpool prices went below 5*d.*, though only for a very short time, the official minimum of 4·25*d.*, which was touched early in December, 1914, is seen to be quite reasonable. Unfortunately, however, this official minimum did not represent the level to which the actual prices fell. In the Cotton Belt, field prices were such as to discourage planters very seriously, with the

* For details see "The World's Cotton Crops," by the writer (A. & C. Black, 1915), p. 112.

natural result that the 1915 acreage was considerably reduced. The final estimate, which was not published until June, 1916, was 32,107,000 acres, as against 37,458,000 in 1913, and 37,406,000 in 1914, and the effect of this reduction of 14 per cent. in acreage was accentuated by the marked reduction in the use of fertilisers for the 1915 crop. The inevitable effect upon the crop was shown by the reduction of the *Chronicle's* figures of the outturn to 12,953,450 bales, against 15,067,247 in the previous year, and it is probable that the relative amount of these two figures would be considerably altered if it were possible to estimate how much of the 1914 crop did not come into sight until after the opening of the 1915-16 season.

4. Following upon this serious reduction of the 1915 supply there came a marked recovery in the demand throughout the world. Our own home trade was probably never better. The demand for linters for gun cotton is very difficult to estimate, but the writer's guess of 1,000,000 bales, which was questioned at the time, is now probably below the mark. The marked expansion of the cotton industry in America and Japan, and probably also in India, was perhaps the chief factor in the increased consumption, and the extent of this may now be estimated from the fact, only recently confirmed by official figures, that the consumption of cotton in America during the season 1915-16 was fully 7,250,000 bales, as against about 5,000,000 bales a few years ago. The result was that the lean year of 1915 ate up a very large portion of the surplus of the fat year of 1914, thus adding another pair of years of alternate excess and deficiency to the ten before referred to.

5. These facts were not realised early enough to put up the price during the winter of 1915-16, and so tempt a record acreage for 1916. Prices in New Orleans were much oftener below than above 12 cents during the winter, and they fell markedly from January to the beginning of March, which is, of course, the most critical period. In the end of February, 1916, the New Orleans price touched 11·13 cents. The effect upon the 1916 crop was a foregone conclusion. The acreage under cotton in America was only moderate, the revised estimate being 35,239,000 acres, or fully 2,000,000 below the record.

6. Unfortunately the course of events in America was paralleled by the conditions in Egypt and in India, and probably throughout the other cotton-growing areas of the world, with perhaps the exception of Russia. The Egyptian Government early in the autumn of 1914 adopted a policy of severe legislative restriction of the 1915 area, which, in the light of subsequent events, can only be described as panic-stricken. As a matter of fact the restriction became a dead-letter, and had to be officially withdrawn early in the spring of 1915, but it at least helped to bring about the very serious reduction in the acreage in Egypt, which amounted to nearly 33 per cent., the acreage being reduced from 1,755,270 feddans to 1,186,004. In India the Government early in the winter had contemplated similar restrictive measures; but these were not pressed, and, indeed, were probably not given effect to at all except in one or two districts. But the economic conditions were sufficient of themselves to produce the same result on the acreage in India, and the actual reduction proved to be nearly 27 per cent., namely, from 24,595,000 acres to 17,967,000.

In 1916 the prospects of the Egyptian crop were early in the season described unofficially in a way which could only be characterised as unduly optimistic. The record acreage of 2,000,000 feddans * and a bumper crop of 8,000,000 kantars were unofficially forecasted; but, unfortunately, these estimates were speedily falsified. The official report of the acreage proved to be only 1,655,512 feddans, being 6 per cent. less than that of 1914. In India it is not possible yet to give any estimate of the full 1916 acreage, but the official figures so far issued show only an increase of 12 per cent. on the figures of 1915, and are, therefore, much below pre-war records.

7. The table given on page 112 summarises these statistics and leads up to the inevitable conclusion. As the season of 1916 advanced, the cotton world began to realise that the prospects of supply were none too good, while the demand was proving beyond all expectation, and it became evident that unless the weather during the growing season remained favourable the expected supply would be barely enough to meet the expected demand. When to this was added the probability of the war coming to an end before the close of the 1916-17 season (July 31st, 1917), it was brought home to the trade that the position of the supply was precarious in the extreme, and that if anything should go wrong with the American crop the supply would be seriously short. As thunder follows lightning, the facts followed this realisation. The weather in America during the summer was just about as bad as it could

* A feddan is roughly an acre and a kantar 100 lb.

be for the cotton crop, and the third of the Government condition reports (as at July 25th) showed such a falling-off from the second as to produce something bordering on panic. Prices began to rise rapidly. The 9*d.* limit was passed in the last week of August, and the shilling on November 17th, and the crisis which had long been predicted by a few so-called pessimists had become an accomplished fact. The world was caught hopelessly short of cotton.

For this serious state of affairs there is practically no remedy as far as the present season is concerned, except perhaps to restrict the necessary consumption as far as possible. The world's cotton crops are almost entirely grown in the Northern Hemisphere, and, therefore, during our summer season. With the exception of South India, Peru and Brazil, they were all sown before the present high prices began, and there is nothing for it but to wait till next year for an increased supply. Then we shall surely have a record acreage in America again, and, with ordinary luck in the way of weather, we should have a bumper American crop next season, which ought materially to relieve the situation, especially if the war drags on through next summer, and there is still no definite date in sight for peace when the new crop begins to come in. But surely the bitter experience of this season ought to be enough to drive home finally the dangers of our being so largely dependent on the American crop for the world's supply of cotton. These disadvantages have often been pointed out, but they may be restated in the light of this new experience as follows:—

(1.) The American crop is no longer able to keep pace with the increase of the world's demand. That is the new feature of the situation to-day. The American area has stopped increasing since 1913, and it is an open question whether, or rather at what price, it will begin again. That it will touch new records again in acreage and quantity is hardly to be doubted, but only at a price that will cover the high cost which now rules the production of cotton in Texas. The war has proved that the South has much greater facilities for diversification of its crops than was generally known, or than was ever true before. The labour difficulty is constantly increasing. The boll-weevil, whose depredations do so much to reduce the profit earned on cotton-growing, is extending its area rapidly north-eastward through the

Atlantic States, and is adding every year to the difficulties and uncertainties of the crop. For it must be remembered that cotton is essentially a speculative crop from the planter's point of view. He never knows in any season what his money yield per acre will be, because it depends in the first place on the weather and the boll-weevil, and secondly on the world's price, over which he seems to have no control. There are, therefore, many planters always ready to go off cotton for a season to a greater or less extent, and only a very high level of permanent prices will again induce the planters, as a whole, to resume the steady increase of cotton acreage which had been maintained for some years before the war.

(2.) The high cost of production of the crop is militating strongly against the continued increase and permanent supremacy of the American crop. This is largely due to the rising cost of labour, which is likely to be maintained, if it does not go on increasing. Cotton has always been regarded as a cheap labour crop, and labour in the Southern States is no longer cheap. America, therefore, has lost one of the advantages which made it an ideal cotton country, and there are now many other countries which, on account of their cheaper labour supply, are better fitted for cotton-growing than America.

(3.) The American crop has developed a sort of regular irregularity or periodic fluctuation in its outturn, which is a very serious fault in the raw material of a great industry. The writer's investigations into the recent history of the crop have brought out the fact that there is a well-established vicious circle in the relation between area, crop and prices, thus: The effect of a large crop in any one year is naturally to reduce the world's price for that season. This discourages the planters, and leads to a reduced acreage in the following year. Thus it will be seen from Table C in the Appendix that there is a very close correlation between the area sown in any year and the price of the previous season, which, of course, is only natural, though its full effects have perhaps not been noted before. The result is to confirm in a way the old Lancashire saying, that a big crop is always followed by a small one, and *vice versâ*. There is a tendency to a see-saw or pendulum movement in the crop from year to year, which is very undesirable from the point of view of the manufacturers, especially in an industry where goods are sold so far ahead as they are in the cotton trade. The strength of this tendency in America is largely due to the fact that many of the planters are working so near the margin of profitable cultivation.

(4.) In addition to this periodic variation of the supply, the amount of the American crop from year to year is rendered still more uncertain by its complete dependence upon the American climate, which is most variable, and which affects the crop adversely or otherwise throughout practically the whole length of the year. Thus the most promising crop may be ruined at an advanced stage of its growth by unfavourable weather conditions, as the 1916 crop has been, and this introduces a further and most undesirable element of speculation into the quantity, and therefore the price, of the crop. (See the fluctuations of the yield per acre in Table C.) The only way to minimise these fluctuations of the price is to develop a much more considerable bulk of the world's cotton supplies in some area entirely removed from the American Belt, where the climatic variations, even if they are no less extreme than those of America, will at least be different, so that all the world's crops are not likely to be affected in the same way in any one season.

All this points to the desirability of developing other sources of supply of cotton outside of America. If at the same time such a supply can be obtained in some other continent, where the labour cost is not so high as it has now become in America, so much the better. Finally, if such a crop could be found somewhere in the British Empire, it would, from our point of view, be the greatest advantage of all. Is such an increase of the supply possible?

To answer this question it is necessary to enter upon a rapid survey of the present sources of the world's cotton supplies. Instead of making the survey in geographical order, it may be more easily followed if taken instead in order of the quality of the world's chief cotton crops. For this purpose the writer has always found it convenient to divide the world's principal varieties of cotton into five grades, into which the recognised trade classifications are grouped. The best cotton of all is the true "Islands" cotton, which is the very best Sea Island cotton, and is only grown in certain small islands off the coast of South Carolina near Charleston and in the West Indies. The total amount of this crop is exceedingly small and its value very high, as much as five or six times the basis price of American Middling being paid for the best "crop lots." It will be seen from the table given on page 114 that the crop is divided between these two sources of supply

in the proportion of one-third from the British Empire and two-thirds from the other source. The same principle of classification is followed out in the table with regard to the other grades. The second grade, also called generically Sea Island, is known as Floridas and Georgias. In this grade may also be included the best Egyptian varieties—Sakel, Jannovitch and Abbassi. The third grade includes ordinary Brown Egyptian, and the best of the long-staple American cottons, while Peruvian cotton comes pretty close to it, and even some of the Nyasaland and Uganda cottons are not far behind, though perhaps more properly placed in the next grade. In both these grades the Empire's share stands very high. The fourth grade is the great bulk of the world's supply, the American crop forming by far the greater part of it, and it will be seen from the table that it is in this grade that the British Empire stands worst; for all that we can show in this class of cotton is a comparatively small amount, say 15,000 bales from West Africa, and that part of the Indian crop which is above the usual Indian quality, and which amounts now to between 250,000 and 500,000 bales. But practically all our rivals are better placed than ourselves in respect of this class of cotton. Russia has a crop of a million bales within her own borders, Germany a crop of 100,000 bales in the Levant under her control, and even Japan has a considerable supply of fairly good cotton of American quality at her own doors in China and Corea. Finally, in the fifth or lowest grade of cotton, the short-stapled native Indian varieties, we again have the enormous but undesirable preponderance; for the Indian crop forms the greater proportion of the total of this class of cotton in the world.

Our position, therefore, is that we stand well in comparison with other countries in respect of our Imperial supplies of the best and the worst grades, but that we are almost entirely

THE WORLD'S COTTON SUPPLY, AND THE BRITISH EMPIRE'S SHARE IN IT.

Grade.	Quality and Staple.	Where Grown.	World's Crops. Bales.	Empire's Share.	Per cent.
I.	*Best Sea Island*	Islands, South Carolina	10,000		
	(Longest Staple)	West Indies	5,000		
			15,000	5,000	33
II.	*Second Grade Sea Islands*	Florida and Georgia	70,000		
	(Long Staple)	West Indies	2,000		
	Best Egyptian (Sakel, etc.)	Egypt	430,000		
			502,000	432,000	86
III.	*Egyptian*	Egypt	1,000,000		
	(Good Staple)	Sudan	25,000		
	Staple American	Mississippi Delta, etc.	200,000		
		Nyasaland, Uganda, and East and South Africa.	50,000		
		Peruvian	125,000		
			1,400,000	1,075,000	77
IV.	*American*	U.S.A.	15,000,000		
	(Ordinary Staple)	Mexico	150,000		
		Brazil	300,000		
		Russia	1,000,000		
		West Africa	15,000		
		Levant	100,000		
		India	250,000		
		China and Corea	250,000		
			17,065,000	265,000	1·6
V.	*Indian*	India	5,000,000		
	(Short Staple)	Russia	400,000		
		China	1,800,000		
			7,200,000	5,000,000	69
			26,182,000	6,777,000	26

dependent on foreign sources for our supply of the " bread and butter " grades, which still form the great bulk, though not perhaps the highest value, of our consumption. Is there then any immediate possibility of our being able to remedy this defect in our position?

Passing over those of our Colonial possessions whose quality places them in the three higher grades of cotton supply, we come at once to Africa and India as the only parts of the Empire which might supply this deficiency. The Egyptian crop is far too good in itself, and far too valuable to our fine-spinning industry, to allow of its being replaced by anything approaching American cotton. The same applies to the Sudan, which is mostly capable of growing good cotton of Egyptian type, and it would be waste to put it into anything of a lower grade. There are, however, certain areas in the Southern Sudan which would probably be very suitable for growing cotton of the long-stapled American type; but it is quite certain that the development of these areas will have to wait upon the completion of schemes intended to benefit the other areas, and that alone will take a good many more years than we can afford to contemplate in our present survey. It will be ten or fifteen years at least before the possibilities of the Northern Sudan, including Tokar and the Gezirah scheme near Khartoum, will be anything like fully developed, and any possibility of developing the other regions in the grain-growing districts of the Southern Sudan must be postponed to that.

In Uganda, again, there are great possibilities; but the difficulties of communication and labour supply, which are the great stumbling-block to the development of all our interior African Colonies, will probably prevent any really great development there for a good many years to come. The largest crop yet reported was that of 42,000 bales of 400 lb. in 1914, and there is no likelihood of that figure being even doubled in the immediate future. Similar difficulties are delaying progress in Nyasaland, where there can be no question of the possibilities of the country, but much will require to be done in the way of improving railway and river communications before the present crop of less than 10,000 bales per annum can be materially increased.

There is only one part of Africa to which we may look for a really large increase of ordinary cotton, namely, West Africa. The magnificent pioneer work of the British Cotton Growing Association there, as well as in the other African Colonies already mentioned, has proved the possibilities of the country beyond doubt. But the provision of communications and the gradual opening up of the country is slow work, requiring a great deal of time and money, and the rapidity of progress has hitherto been checked by the fact that the local variety of cotton was just not quite good enough to make a really conclusive comparison, from the point of view of the grower's profit, with other competing crops which have the great advantage of requiring less care and labour for their cultivation. The African native is wise in his day and generation; his needs are few and very easily satisfied, and he is not easily tempted into the growing of crops which make serious calls on his limited energy. His food crops are easily grown, and he grows just enough cotton to make his own clothing, which is not over-abundant in quantity. But within the last year the situation seems to have changed very markedly in Northern Nigeria owing to the introduction of a new variety, which gives a much better return because of its higher yield and ginning outturn, and better quality, and which, therefore, seems to have caught on remarkably with the natives, with very encouraging results. The area available in Northern Nigeria is immense, and it may be hoped, now that the corner has apparently been turned, that future development will be much more rapid. It would be self-deception, however, to pretend that there is any prospect of a really large immediate increase of the supply from this country which would make an appreciable difference in the present position of the cotton industry. What the world wants is a progressive increase of something like a million bales per annum, and there is no possibility of such an increase being obtained from Nigeria, or indeed from any part of Africa, within the next ten or fifteen years at the least.

It is, therefore, to India that we must turn as the only hope for relief in the way and to the extent which the cotton industry requires so urgently.

India suffers sadly from her evil reputation in the matter of cotton-growing. Everyone knows the old story of the alleged prayer during the cotton famine in the sixties for " more cotton, but not from Surat," and ancient as the story is, it still represents the feelings of most people in Lancashire. They cannot believe that any good cotton can come out of India. Unfortunately this belief has its counterpart in India. Just as everyone in Lancashire

will tell you that it is no use trying Indian cotton, it is always short in staple and in very dirty condition, so most people in India will tell you that there is no use in their trying to grow superior cotton, because no one will buy it from them, especially Lancashire. But what are the facts? India to-day is growing from 250,000 to 500,000 bales of very fair cotton, similar to American in quality and of nearly an inch in staple, sometimes more, which is quite fit to be used in Lancashire, and which is, as a matter of fact, very largely used both in India and in Japan at the present time in place of American. As a matter of history the evil reputation of Indian cotton is of comparatively modern growth, and practically dates from the beginning of the nineteenth century. Up till about 1820 India actually supplied the bulk of the Lancashire cotton consumption, and it was only when the American crop began to increase rapidly and to find its way into England in large quantities that the Indian cotton began to be displaced. From the first, however, it is interesting to notice that one of the chief advantages claimed for the American cotton was its greater freedom from dirt and foreign matter, due to the method of ginning it or separating the lint from the seed. Ever since 1793, when Eli Whitney invented the saw gin, that alone has been used in America (except for Sea Island and other long-stapled cottons), while India has persistently adhered to modified forms of the old churka or roller gin, though, as a rule, it is no longer operated by hand. It is one of the puzzles of the cotton industry that, whereas in America it is impossible to persuade the trade that the saw gin is likely to harm good staple cotton, and should not be used for anything much above an inch in staple, all over India it is universally held that the saw gin "gin-cuts" even the short-stapled Indian cotton. This is not a mere matter of unsupported opinion, for as a matter of fact some of the Dharwar-American type of cotton grown in the Punjab was saw-ginned at first, and was rejected repeatedly by the Karachi and Bombay dealers as gin-cut, and samples of American cotton from Sind, which the writer himself saw in the Punjab last winter, certainly did seem to be badly spoilt in that way.

Saw gins are only used to any extent to-day in India in the Dharwar district, where presumably, like the local Dharwar-American cotton, they are a relic of the introduction of American seed and methods in 1840; but even there they are now being replaced by the ubiquitous roller gin. The only opinion the writer can hazard on the question is that the ginners in India do not know how to get the best results out of a saw gin; and that is by no means unlikely, judging from his experience (at secondhand, of course) of the difficulty of getting the best results out of the roller gin in Egypt.

This question is of more importance than it seems, because it is largely the question of the condition of Indian cotton that tells so strongly against it in English markets, and that is chiefly a question of ginning methods. The inferiority of the staple is, however, a more serious matter, and this question, too, is by no means new in India. To begin with, there is the ancient tradition of the Dacca muslins, which were made in India from cotton grown and spun in the country, though the writer was unable to find out where the cotton is supposed to have been grown, and what has become of the particular variety of the plant that produced it. But the allegation is frequently made that cotton as fine as 300's, or as fine as the best products of the Lancashire mills to-day working on the best Sea Island cotton, was habitually produced in India long ago. Even allowing for the exaggeration of tradition, it is difficult to reconcile this statement with the fact that the great bulk of the Indian cotton to-day is only about $\frac{3}{8}$ in. to $\frac{5}{8}$ in. staple. That, however, is by no means the best that India can do, even to-day, and in every generation there have been a few enthusiasts who have retained their belief in the possibilities of improvement of Indian cotton, and have struggled against great difficulties to prove the faith that was in them. Thus in the forties of last century, under the auspices of the East India Company, great efforts were made to introduce superior varieties into India, especially in Dharwar; and these efforts met with such success that to-day the descendants of these Dharwar-American cottons are still among the best cottons in India, and have recently become the parents of many new varieties such as the Punjab-American cotton. Again, during the cotton famine of the sixties, strenuous efforts were made in various parts of India by the Manchester Cotton Supply Association to increase the quantity and improve the quality of the Indian crop; but their success, though very encouraging, was not sufficient to outlive the subsequent depression of cotton prices in the early nineties, when Indian cotton probably reached its lowest ebb. But there are still evidences remaining of

the work of these pioneers, and the renewed efforts which have recently been made by the Government Agricultural Departments in almost every province of India have led to the production of a large number of improved varieties, and some of them in considerable commercial quantities.

From the point of view of cotton-growing, Madras is certainly the best part of India, the "Benighted Presidency" showing a long lead over the others in the matter both of quality and quantity of staple cotton. Tinnevelly, which is largely grown in Southern Madras, is quite a satisfactory cotton, a good deal of which found its way to Liverpool before the war; and the latest discovery known as "Cambodia" promised at first exceedingly well, being of very satisfactory staple, and otherwise a very good cotton. It is, unfortunately, showing signs of deterioration in quality, like so many others everywhere; but this is the universal tale of new cotton all over the world, for it is one thing to produce a new and improved variety of cotton, and another and much more difficult thing to keep it reasonably pure under field conditions. India, however, is probably rather worse than its rivals in this respect, for one reason. The ginning of the crop in most parts of the country (Madras, by the way, provides many exceptions) is in the hands of small native firms, or individuals who seem to be incorrigibly addicted to all the vices of the handlers of cotton throughout the world, especially the worst vice of all—that of mixing good cotton with bad in the hope of selling the whole at the price of the superior variety. More time and money have been lost in that way than by almost any other piece of dishonest dealing in the world; for the inevitable effect is to bring the whole crop in a very few years down to the level of its worst components. But in Madras, in 1916, an attempt was made to introduce a system of handling this abuse, which deserves to be advertised, whether it succeeds or not, as a model of what might be done by trade organisation on the right lines. A short-staple variety known as Pulichai had been introduced into the Tinnevelly district, which is entirely devoted to staple cotton, and at first it caught on very well, because it yielded quite as well as the longer stapled variety, and gave a slightly larger ginning out-turn, and as long as it could be passed off successfully by mixing with the superior variety of the district it paid the growers very well. But the cotton trade in Madras is largely in the hands of European firms of standing, who had sufficient foresight to see that such methods would very soon defeat their own ends, and incidentally destroy the whole superiority of the crop of the district. In consultation with the Director of Agriculture for the province, Mr. D. T. Chadwick, they entered into an agreement that, after having given the growers ample warning of their intention, they would after a certain date refuse to purchase at any price cotton which contained any admixture at all of the Pulichai, and fortunately it was easy to tell, owing to the different character of the seed, when such admixture had taken place. Some of the growers, with their usual disregard of such threats, calmly went on sowing mixed seed as before; but when the ginning season of 1916 came round they found to their surprise that the dealers meant what they had said, and would not buy the mixed crop. The crisis had not reached its final *dénouement* when the writer left the district; but it is very much to be hoped that the determined stand taken by the authorities of the trade was successful, not only as a warning to the growers of the district, but also as a precedent for other districts. It is very much to be regretted that conditions elsewhere do not permit of such methods being generally applied, because in most cases the ginners are small men and numerous, and it is impossible under present conditions to deal adequately with this problem of mixing. Until something is done, however, there will be no serious possibility of improving the Indian crop. Every attempt made by the Government Departments to introduce new and improved seeds is stultified by such practices, which pay nobody in the long-run.

This difficulty merges into another. It is exceedingly difficult to get the trade in most parts of India to recognise the value of good staple cotton, and to encourage its growth by offering a good price for it, especially in the early stages. This is, of course, not confined to India—the same difficulty is met everywhere; but in India there is a serious lack of any public-spirited body which is prepared to shoulder the burden of helping a new cotton through its early years, when, owing to the small quantity available, it is not worth while for any merchant as a business proposition to pay its real value for the small quantities which are all that is obtainable. But this attitude seems to have developed in certain parts of India into a confirmed habit of mind which refuses to

recognise the value of staple at all. It is very striking how all over India one finds the tendency to value cotton, not by the length of its staple, but by its ginning outturn. Thus in two districts of Bombay, the writer found superintendents of experimental farms deliberately selecting cotton for their ginning outturn alone, regardless altogether of staple as a factor in their value; and this is attributed to the general attitude of the trade in India. The excuse of the officials is always the same, "The trade won't pay for staple," and it is perfectly true. There are honourable exceptions, of course; but the greatest difficulty that the breeder of new cottons has to meet is the apparent impossibility of getting anything like a fair premium for improved staple cotton, with the result that the growers will not take up the improved varieties. It is only fair to add that there is one notable case in which this attitude of the growers is probably justified. In the Central Provinces there has been developed in recent years a remarkable variety of short-stapled cotton called *Roseum*, which possesses probably the highest ginning outturn of almost any cotton in the world, running sometimes over 40 per cent. (against a maximum of about 33 per cent. in almost every other country). At the same time it gives such a heavy yield per acre, compared with other longer stapled varieties of the same district, that there is simply no question between the two, especially as the staple of the *Roseum* is not so very short after all, being well over ½ in., while the usual native varieties such as Bengal are generally below that. But the writer's feeling in going through different provinces in India was that in other districts the example of the Central Provinces is too often followed where the conditions are by no means so conclusively in favour of that course. There can, of course, be no question that the duty of the Agricultural Department is to give the cultivator the cotton which will pay him best, in view of all the factors which go to make up the value of the crop, including yield per acre, ginning outturn, staple and price; but the tendency in many cases seemed to be to go for ginning outturn alone, because the growers and the trade would not pay attention to anything else, although the agriculturist knew that there was another variety which *ought* to pay the cultivator better if the trade would only give the grower its fair value. Thus staple has been neglected for ginning outturn, and as the two are practically opposing factors, the weight of the Government influence has in effect been thrown into the scale of short staple because it was the line of least resistance. The disadvantages of this policy, or rather of this acceptance as inevitable of admittedly undesirable conditions, are shown by the experience of two different provinces. In Bombay there seems reason to believe that, both in the Dharwar country and in Broach and Surat, there is a distinct tendency towards the loss of staple, while in the Punjab the very same Dharwar cotton has been distinctly improved, and a market has been made for it by the adoption of methods which have compelled the trade to recognise its superior value. This has been done by the system of Government auctions for the improved cotton, and when the local trade attempted to boycott these sales the representatives of large outside firms were brought up to the Punjab from Bombay and Nagpur, and made even higher prices. The result was that last year the premium for American cotton over the ordinary *desi* variety was over 50 per cent.

One cannot help feeling that the prospects of improvement in India are better just in proportion as that spirit has been developed. The apathy of the trade is, perhaps, the greatest difficulty of the whole matter; but it cannot be allowed to spoil the prospects of improvement, especially in a new district like the Punjab, where the possibilities of improvement are so great; for the Punjab is in a way the most promising district in all India at the present moment. The improvement of the irrigation facilities due to the completion of the great Triple Canal System, which has already been described in this Society's records, is one of the greatest achievements in the direction of cotton-growing under irrigation in the world, and its effects upon the Punjab crop are bound to become increasingly apparent. The great *doabs* lying between each pair of the Five Rivers are now being converted into fertile areas, much of them suitable for cotton-growing, where there was nothing before but glaring desert and the scantiest monsoon cultivation in patches. That the Punjab can grow large quantities of good cotton is now beyond question; but the trade cannot be left to itself to handle the crop in its own haphazard way.

It is unfortunate that the rapid development of irrigation facilities in the Punjab has inevitably been, to some extent, at the expense of similar schemes lower down the Indus in Sind. This is a subject which has also been fully dis-

cussed before this Society, and the writer need say no more than that the prospects of large development of cotton-growing of the best kind in Sind are assured as soon as the water supply can be given by the completion of irrigation works. It does seem tantalising that, with the world crying out for more cotton and willing, as it is now, to pay a high price for it, an enormous area such as Sind should be lying desert, where, with the expenditure of a few millions, a magnificent crop of cotton could be grown which would probably pay for the cost of the necessary works in a few years. Sind has well been described as a second Egypt, and it is a pity that its development could not be pushed on as rapidly as has that of Egypt during the last twenty years. But India suffers from the fact that it is so huge a country, and that it has been in the past a very poor country, and outside capital for its development has not been available in sufficient quantity, so far at least as cotton is concerned.

That, indeed, brings us to the crucial point of the whole cotton problem in India. The position is changing rapidly, and the methods to be adopted will require to be changed too. Until comparatively recently it was not at all sure whether, taking both political and economic considerations into account and under the conditions generally existing, cotton really did pay any better than plenty of other crops. But the recent rise in the price of cotton must have completely changed the position, and there can hardly be any doubt that at anything like present prices cotton, especially good cotton, would pay India better than any other competing crop. The problem is therefore, first, whether such prices are likely to last; second, how the improvement of the quality and the increase of the yield of the Indian crop are to be secured; and, third, how the full value of the crop is to be secured to the cultivator in face of the inertia and apathy of the trade towards improvements.

As to the first question, the writer has already stated his belief, and the reason for it, that we are in for a long spell of high cotton prices. The real basis price of cotton is the price in New Orleans, and that will not fall much or for long below 12 cents per lb. The second problem is one for the Government to consider. It is useless to expect the conditions in India to change of themselves. The Government must do something, and two possible lines of action may be suggested. In the first place, however, it is necessary to guard against giving the impression that the Government have done nothing, or are not willing to do anything that lies within their power. On the contrary, they have spent money freely on the development of agricultural colleges and on experimental and demonstration work of various kinds in agriculture; but they have not yet found courage to go to the root of the matter, which lies in the fact that the trade will do nothing towards the necessary reforms on its own initiative, and that the growers, including the Government Departments of Agriculture, *can* do nothing against the inertia of the trade in a country like India. The obvious conclusion, therefore, is that the Government must do something more than they have hitherto attempted, and that either by exercising compulsion towards reform or by setting an example themselves on a large commercial scale. On these lines the writer desires to put forward two definite and practicable proposals for immediate reform which the Government might reasonably be asked to take up at once.

The first is that the Government should introduce a system of licensing and control of the ginneries, which would give them power to put a stop to such practices as damping and mixing cotton and allowing dirt to find its way into the bales, even if there be no truth in the tales of still more extreme practices in that direction. The method of handling the loose bale from the ginning room to the press, which the writer himself saw in a ginnery in Dharwar, was enough. The newly ginned cotton, in a loosely made cover of sacking, with its contents projecting at every corner, was deliberately rolled over and over in the dust of the ginnery yard, which, of course, was inches deep, from the gin room to the press, a distance of apparently at least a hundred yards, and by the time it reached its destination it was hardly possible to distinguish between the colour of the cotton and that of the jute bagging in which it was wrapped. Again the answer to all protests is the same —"The trade does not object, and will not pay for clean cotton." To introduce compulsory control of this kind would, perhaps, be a new departure in India, but it is no new departure in the cotton world. It has been done in Egypt with satisfactory results. It has been done in the Sudan with the result of adding pence per pound to the value of the Sudan cotton. Surely it is no stretching of the limits of good government to compel abstention from practices which are dishonest as well as short-sighted.

Second, the Government must, either of itself

or through some suitable agency, show, on a considerable commercial scale, how a cotton plantation could and should be worked, and the opportunity has arisen under ideal conditions to make such an experiment. Two years ago the Government of the Punjab, on the occasion of the third visit of the indefatigable secretary of the International Cotton Federation to India, were persuaded to offer to the Federation a piece of land extending to 7,500 acres in the Lower Bari Doab Canal Colony for the purposes of a seed farm and model cotton plantation on terms which would have enabled a really satisfactory experiment to be made. Unfortunately, owing to the war it was impossible for the Federation, which includes Germans and Austrians in its membership, to take up the offer; but the Punjab Government next offered the concession to the British Cotton Growing Association, which still has it under consideration. If they unfortunately cannot see their way to take it up and find the necessary capital, which need not be very large, for carrying out the scheme, it is most earnestly to be hoped that the Government of India will see the advisability of doing it themselves. What is wanted is to test the question of cotton-growing in India in every respect, by growing the best cotton that can be grown under irrigation conditions in the Punjab, picking, ginning, baling, and generally handling it in the best possible way, and putting it on the best possible market wherever that may be. There are many in India who maintain that Indian cotton should be retained for manufacture in India alone—just as there are some in Lancashire who refuse to take any interest in cotton-growing in India unless the cotton is to come to Lancashire. With such narrow views on either side the writer has no sympathy whatever. Let both markets be tested, and let the best price win. If it be true, as it may well be, that India, owing to the handicap of the high freight, can afford to pay a higher price on the spot for good staple cotton than Liverpool, then by all means let India keep the cotton, if she can employ it to the best advantage, and there are indications that India is developing rapidly in the direction of finer spinning. The best of the large firms in Bombay have realised that the competition of Japan in the coarser counts is telling very severely on the Indian trade, which was chiefly in that branch, and that if the Indian industry is to be saved, let alone developed, it will be by following the example of England, and gradually working up to a superior class of product. Japan herself is showing the wisdom of that course, and is steadily working up towards fabrics a good deal above the grade of the cheapest of the cheap with which she has recently been flooding the Indian market, and even to some extent our own in this country. The development of the Japanese industry since the war would make a study in itself; but here we must confine ourselves to the actual and probable effects of it upon the Indian industry, both as regards cotton-growing and cotton manufacturing. Japan has certainly been the best outside customer for Indian cotton, especially the staple varieties, since the war. She has bought Punjab-American and Madras cottons very freely, following her usual policy of buying in India when American prices are dear, and especially now with the additional handicap of high freights on the more distant crop. It is quite likely, therefore, that Japan will prove to be a very keen competitor for any increased supply that may become available of staple varieties of Indian cotton. But the writer's contention is that there should be no discrimination in favour of or against one purchaser or another. The object of the scheme is, in the interests of India, to find the best market available for improved Indian cotton, and no other consideration should be allowed to come in the way of that object. He still believes that in the long-run the cotton will come to Liverpool, because Lancashire is always the best market for cotton, especially good cotton. But even from the selfish point of view, if it should prove otherwise, it would still be to the gain of Lancashire to see such a new source of supply of cotton developed though she never handled a bale of the product. It cannot be too often repeated that the basis of the whole situation to-day is a world shortage of cotton, and every bale of cotton produced anywhere is so much to the good, whether it be consumed in the country where it is grown or exported somewhere else. The only condition which sound economics dictates is that the cotton must be used to the best advantage.

In passing, it may be noted as an interesting feature of the war situation that a considerable quantity of Uganda cotton has been imported into India recently, and that the better class of Indian mills in the Bombay and Ahmedabad districts competed keenly for the supply. Here, again, the handicap of freight has, of course, told heavily in favour of the Indian purchaser, especially because there is frequently a consider-

able volume of shipping running light from East African ports to India, which is glad to pick up an odd lot of cargo like cotton, and there is some possibility that this trade may develop. But it is also to be taken as another straw showing which way the wind blows in the Indian cotton-manufacturing industry.

The many-sided character of the question of the best market for Indian cotton which has thus been raised is another argument for the experiment which the writer is advocating; but, whatever may be the result on that point, the success of the Punjab scheme is assured, and it would very quickly be made a precedent for other provinces to follow. For it seems beyond doubt that practically nothing can be done to meet the present situation in India adequately except by vigorous Government action of some sort. For years the Government have exhorted the cultivator to improve his methods, and have demonstrated and offered to assist in the adoption of better ways, but with comparatively little effect. It is beside the question to discuss where the responsibility for this comparative failure lies, or how it should be distributed. It is idle to blame it entirely on the growers or entirely on the trade, and certainly the time was not ripe till now for the Government to step in and take action which could only be justified by the proved failure of private enterprise to achieve reform itself. But that failure is now definitely proved, and the question is simply whether the Government will take action, or allow the whole thing to go by default. For the fact must be faced that, if reform is to proceed at the present snail's pace, it will be generations before any substantial improvements can be effected, and by that time it may be too late for India to reap the benefit which is now offered to her. It must be remembered that India has a very serious prospective rival in the enormous undeveloped areas of Africa. Nigeria, once it is fully developed, will run India very close as the ideal cotton country—in fact, except in the matter of population, India has probably very little advantage, except time, on her side. What the world wants is an *immediate* increase of the cotton supplies. India alone can possibly meet that need. If she does not take her chance now she may be too late later on.

It would be foolish, however, to pretend that the proposals which are here put forward are free from considerable difficulties. The first and worst of these is probably that of finding the necessary staff. For years it has been dinned into the ears of the Indian Government that the staff of the Departments of Agriculture was ludicrously inadequate. The writer came across an instance of this in one province, where a young Deputy Director of Agriculture had a district of 25,000 square miles (more than twice the whole cultivable area of Egypt) to look after, in which he was responsible for the supervision of all the crops, not merely cotton. It will take him probably all the years he will spend there to get through the whole of his district once. But the Government are now fully alive to this necessity, and are doing what they can to meet it. Unfortunately, their change of policy came just too late, for the war has taken away some of the existing staff and all of the type of young student at home who might have been tempted into such appointments, and now the supply is practically dried up for some time to come. The same difficulty would apply to the question of the proposed control of the ginneries. There is no staff available for the work, except perhaps in one Department—that which administers the Cotton Excise Duties. To those who know anything of the attitude of India on this question, it need hardly be explained that they would very willingly dispense with the services of that Department; and its abolition might even reconcile them to what they would otherwise regard as an intolerable interference with the liberty of the subject in the control of the ginneries.

To sum up, India is the only country in the world from which there is any hope of obtaining an early if not immediate increase of a million bales per annum of new cotton, and there is every reason to believe that India could maintain such an increase cumulatively till her present crop was at least doubled. As will be seen from Table D in the Appendix, the area under cotton is immense—over 25,000,000 acres in 1913-14, or two-thirds of the whole area under cotton in America, though it may be noted in passing that, as will be seen from Table E, the increase of the Indian crop has hardly kept pace with that of the American over the last thirty years. Quite apart from any extension of this area, the crop could easily be increased by a gradual improvement of the yield per acre, which is the lowest in the world, only about 85 lb. per acre against nearly 200 lb. in America, and about 400 lb. in Egypt. That such an increase would pay India handsomely at anything like present prices of cotton is beyond question, and it could be done without interfering at all seriously with India's essential

supplies of other crops, especially food supplies. To effect such a change in the Indian crop is a very big problem full of practical difficulties, which, however, are not utterly insurmountable. It will take a good deal of time and money to make the change, but it would take more money to get the same results in any other part of the world, and it probably could not be done at all in the time anywhere else. It is not, however, merely a question of growing an extra crop in certain parts of India, but of steadily and continuously improving the Indian crop a little all round, both in quantity and quality, by the adoption of better methods and the use of improved seed. That means constant and sustained effort on the part of every one concerned in agriculture in India and a very much increased staff, backed by determined action on the part of the Indian Government in the direction of compelling reform of dishonest methods, and showing an example itself on a commercial scale of how things could be and ought to be done. It will take something little less than a revolution to convert the Government of India to such a change of their long-established policy; but steady pressure must be exercised in that direction in Lancashire, in Parliament, at the India Office, and wherever the interests of our Empire and our great cotton industry are considered.

In thus pressing the interests of India on public attention, one must not forget that equal importance attaches to the development on similar lines of all our other Colonies. India comes first, in the writer's opinion, because cotton is already an established and developed industry there, which only needs encouragement and redirection to produce immediate results. But the development of Africa, which means the development of railway, river, and road communications throughout the whole of that enormous continent, must keep pace with that of India. It is largely a question of expenditure. Literally hundreds of millions could be spent on the development of Africa, and profitably. For it is one of the consolations of this very arduous task that everything that is done to encourage the development of new cotton fields is leading directly and equally to the development of every other crop that these new countries can produce, and to their advancement in every respect that means civilisation. The writer was much struck by the remark of an official in a most successful cotton district in India—that wherever cotton appears wages and the standard of living of the cultivators immediately begin to rise, the only drawback of that rise being that the cheap labour which is so much in favour of Indian and African cotton-growing promptly becomes comparatively scarce and dear. But there is so great a margin between the rate of wages current to-day in the Southern States of America and those in India and Africa, that it will be a very long time before the rise in the latter countries can make cotton-growing as difficult as it now is in America. One can hardly imagine the rate of wages in India rising to the dollar or dollar and a half per day which is now the current level in Texas. The pity of it is that this enormous rise of wages in America has not led to anything like a corresponding improvement in the status of the American negro as a man. His expenditure has increased in proportion, but is in many directions foolish in the extreme and of a kind likely to do him and his family the least possible good. It is of the first importance that such a state of affairs should not be allowed to reproduce itself in India or Africa, and, unkind as it may seem, it is probably true that the only way to prevent it is to hope that the rise in wages there may be gradual, so that the cultivators may learn to use their increased earnings wisely as they go along. For it must be emphasised at every turn that our chief anxiety in this proposed development of cotton-growing in India and our other Colonies must be to see that the interests of the cultivators are adequately protected in every way—that they are indeed made our very first care. We must guard against the accusation that we are only seeking to develop cotton-growing in these countries in order to secure the necessary supplies of raw material for our own industries. That it will have that result is, in this view, only incidental. The writer would be no party to any campaign for the development of cotton-growing throughout our Empire if he were not thoroughly convinced that in this matter the best interests of the old country and the new are identical, and that our need is their opportunity.

Finally, he would once more emphasise the great need for immediate action. The present situation is critical in the extreme. It is probable that it will appear less critical before long, because large crops throughout the world next year will ease the present scarcity and lead to a fall in prices again, though only to a level which will still be comparatively high. But we must not be lulled into a false sense of security by such a fall. As long as the world remains so largely dependent on the American cotton crop we shall at any moment be open to a repetition

of the disastrous conditions of this season; and that is a state of affairs which can no longer be tolerated. This time the question must be fought to a finish. The remedy lies in our own hands. It will cost time and money—much money, perhaps as much as we are spending on this war in the course of a few days; but it will be a better investment than that, and it will pay all the better the sooner it is made. Every pound spent now will be worth a hundred a few years hence. The question is one which will not wait till "after the war."

APPENDIX.

TABLE A.—THE WORLD'S COTTON CROPS, 1902-1916.

IN BALES OF APPROXIMATELY 500 LB.

Season.	America.	India.*	Egypt.	Russia.	China.	Others.	Total.

For sources and details see "The World's Cotton Crops," Statistical Appendix A.

The very high figures officially quoted for the Chinese crop a few years ago are now generally discredited. No reliable information whatever is available. The figures in *italics* are the author's estimates only, very little statistical information or none at all being available.

* These are the Government estimates, which are notoriously understated. On the other hand, Indian bales are only 400 lb. weight. Taking the Government figures as 500-lb. bales, as is done here, probably offsets the under-estimation fairly well on the whole, though roughly. The following table from the *Economist* of September 23rd, 1916, seems to justify this approximation.

Season.	Government Estimate.	Approximate.	Actual Crop.
	400-lb. Bales.	400-lb. Bales.	500-lb. Bales.
1908-1909	3,691	4,744	3,795
1909-1910	4,718	5,341	4,273
1910-1911	3,853	4,974	3,979
1911-1912	3,288	4,643	3,714
1912-1913	4,610	5,019	4,015
1913-1914	5,065	6,684	5,347
1914-1915	5,209	5,279	4,223
1915-1916	3,819	5,559	4,447
Average	4,282		4,224

DISCUSSION.

SIR GEORGE TOULMIN, M.P., said he had endeavoured in a small way to impress upon the Colonial Secretary and the Secretary for India the very great importance of this subject as one of those things which should not be allowed to drop even during the war, but very little success attended the efforts which were made by two or three members of the House of Commons. He was rather more interested in the Colonies, perhaps, although he agreed with Professor Todd that if we were to get one million bales additional supply we were more likely to get it from India than from the Colonies. He was quite sure that a generous policy in this matter would pay. It was not possible to leave it in the hands of private enterprise; and although, perhaps, it was a curious policy to be advocated by a Radical, nevertheless he thought a policy of benevolent despotism was necessary in India. Looking at the matter from the Lancashire point of view, whilst they must in that district look at it from their own ideas, he believed there was sufficient public spirit there not to confine that interest in any one of the great outlying portions of the Empire just for their own selfish ends. He rather held that wherever suitable cotton was grown the reaction of the growth of that cotton must be to secure plenty for Lancashire. The licensing of ginneries, as suggested by Professor Todd, was a very practical suggestion, and a fit one for the Government. Similarly, what were certainly fraudulent practices, such as mixing, damping, and the admission of dirt into the cotton, were also matters coming within the duties of the Government. Again, nothing could be more valuable than the combination of the seed farm with the cotton plantation. As to whether India or the Home Treasury should be responsible or not for the finances of any such scheme, the Indian Government should not be slack in supporting even more fully than they had done any such proposals as had been made by the author, seeing that India would benefit very largely by the results. The great object was to secure a grade of cotton which was suitable for Lancashire and which could be relied upon. If that were done it would very soon become a commercial success.

Sir Louis W. Dane, G.C.I.E., C.S.I. (Ex-Lieutenant-Governor of the Punjab), said there was a great field for increased cotton cultivation in India, more especially in the provinces in which he served for thirty-seven years. Within the last twenty years the area irrigated by the Government canals had been increased by eight million acres, the bulk of this area being previously uncultivable desert with a rainfall of less than sixteen inches a year. This soil only needed water to make it first-class for cotton-growing. To his personal knowledge since the early eighties, all the district officers of India had been trying to do their best to secure cotton suitable for the Lancashire requirements. At first they were told that their salvation lay in growing Egyptian cotton, but it was found that the climate of the Punjab, strange to say, was too cold for this. During 1885 and 1886 a khaki cotton was grown which relieved them of the necessity of having to dye it, but this, although very excellent as regards colour, was shockingly poor in quality and quantity of outturn, and it had to be abandoned. In later years attention had been given to the American cotton which was found to grow properly, and, as Professor Todd had mentioned, the Dharwar-American type of cotton was now doing fairly well. The difficulty of it, however, was that it hybridised, and all sorts of proposals had been made to prevent this in actual cultivation. One of the suggestions of the Punjab Government was that, in connection with the Triple Canal scheme in the Montgomery district, a certain area of Government land should be reserved specially for the cultivation of this new variety which, after years of experiment, the Agricultural Department had succeeded in making fairly suitable. It was proposed that on an area of something like 90,000 acres a certain proportion of this cotton should be grown, or that any cotton grown should be that selected by the Agricultural Department. He believed that the proposal was still being considered, but owing to the war it might not be possible to carry it out in its entirety as had been suggested by himself. He had also proposed, as was pointed out in the paper, that an area of 7,500 acres should be granted on special terms for cotton-growing, and he was sorry that circumstances had prevented the International Federation from taking it up. There was no doubt that the land was available and the water was available, and the country could very easily put the million bales suggested by the author on the market in a short time. The population in the area now being irrigated was under 200 to the square mile of cultivation, but, when properly irrigated, this area would be easily capable of holding a population of 700 to the square mile of cultivation. Consequently there was a wide margin for non-food crops such as cotton. Perhaps the author had not given so much attention as he might have done to the extraordinary variations in the climatic conditions in India which made cotton a risky crop. Want of rain even on irrigated land was often fatal, and early frosts ruined the outturn. Then, again, the boll worm caused considerable trouble, but the Government entomologists had discovered a fly which, fortunately, preyed upon the boll worm just as the boll worm preyed upon the cotton, and the difficulties originally encountered of hatching out these flies before the boll worm hatched out had now been overcome. Much had been said of the rudimentary agricultural methods of India, but there were reasons for this. For instance, in regard to water-lifting, many of the wells in India would not stand pumping, and although most of the forms of water-lifting adopted in Egypt had been tried, they were not very much more successful than the indigenous water-lifting methods of India. They generally required expensive machinery in the shape of bullocks, and they were too costly altogether. Even if motor pumps could be used, and he believed that this would be the best solution for wells in Upper India able to stand the pump, the cost of transporting the necessary fuel 1,100 or 1,200 miles made them prohibitive at present. As to damping cotton, he had been asked to introduce a Bill into the Punjab Legislative Council to render it penal to do this. On going into the matter, however, he found the rather curious thing that the Punjab climate was extraordinarily dry, and the growers could not get enough cotton into the bale to draw the full weight, and a bale of cotton was paid for on the number of pounds it contained. When they reached the coast these short-weight bales absorbed quantities of moisture from the sea air, and the buyers were then able to sell bales of greater weight than those they purchased. Consequently, the growers thought they might as well put some water on the bales themselves before they sold them in the first instance. That was one reason why cotton was damped. He agreed that the ginning arrangements in many provinces were exceedingly defective, and probably no great improvement would be manifested without that benevolent despotism which Sir George Toulmin had referred to, and nobody would object to that at all seriously. At the same time he did not wish it to go forth that the Government of India had neglected this question. It was doing the best it could, and in the new irrigated portions of the Punjab there was still an immense field for cotton-growing. He assured them that the Punjab Government, under his very eminent successor, Sir Michael O'Dwyer, was doing all it possibly could to improve and extend the facilities for cotton cultivation there.

Mr. D. T. Chadwick, I.C.S., referring to the additional one million bales mentioned in the paper, pointed out that the author had first said there must be one million bales of high quality, but later he rather inferred that he wanted a million bales of any sort. The author had also laid to the charge of the ginneries the chief blame for all mixing. In that Professor Todd was largely correct, but the questions of mixing and marketing were not so simple as it might appear from the paper. It might seem heretical here in London to say that he was not at all certain that the trade of the world was agreed as to what "quality" in cotton meant. In Lancashire and London it meant long staple, but in India he knew European buyers who laid more stress on colour than on staple. That touched the question of marketing very closely, because it obviously made it much more difficult to check mixing if the large buyers were not agreed as to what exactly they wanted. Professor Todd had mentioned the difficulties experienced in marketing small quantities of better-staple cotton. With any new introductions or improved types the quantities coming on the market in the earliest years must necessarily be small. It was broadly true of all the provinces of India to say that in introducing such improvements it was only the mills in India which rendered assistance in the early years. To them and not to the export houses belonged the credit, if any, if these improvements became established on a commercial scale. Certainly Cambodia—or, as Liverpool called it, "Tinnevelly American"—would never have been heard of but for the interest displayed in it from the start by Messrs. A. & F. Harvey, Indian spinners. Many efforts had been made to deal with this difficulty of marketing. In Sind a buying agency was tried. In the Punjab the officers of the Agricultural Department collected the better cotton at different centres where they organised auctions for it. But in most cases resort was being had more and more to joint sales by villagers to particular buyers. Anyone who had had experience of organising co-operative sales of agricultural produce by farmers, would know how difficult it was to make that system a stable one, and to what insidious dangers it was exposed. That it possessed great possibilities might be illustrated from experience in Tinnevelly, which would also serve to illustrate the length to which officers of the Agricultural Department had been compelled to go to meet this difficulty of marketing for quality. The seed of an improved strain of better quality, and yielding 4 per cent. more lint than the local variety, was distributed. All the farmer got was the extra money for the little bit of extra quantity. He could get nothing for the better quality until the local mills agreed to pay a fixed premium of Rs. 3 on the produce of this seed brought to them direct by the growers. This meant they were paid at a rate of about Rs. 183, instead of about Rs. 180. Officers of the Agricultural Department went with the villagers to the mills and vouched for the cotton. The firm were so satisfied that next year they offered Rs. 5 premium. Next year the premium opened with five and closed with six—other mills were getting interested. The cultivation of this strain was extending, and in this year—1916—export houses began to display interest in it. The season opened with a premium of Rs. 10, and when he left India last June it had reached Rs. 16. It was obvious when such a system as this became widespread it made great demands on the staff to supervise it. He, personally, was afraid that this premium of Rs. 16 would tempt some to mix their seed, and the whole system might get beyond the strength of the present Agricultural and Co-operative Departments to cope with. The Agricultural Departments in India had been led on from experimental, selection and demonstrational work, to the business of seedsmen on a large scale, and finally to the organising of auctions and the fostering of co-operative sales of produce. To cope satisfactorily with such varied duties demanded a very large increase of staff. Professor Todd asked for another million bales, and in support of the possibility of it he laid stress on the actual price of cotton at the moment. He feared that statement was hardly a complete one. It was not so much the actual price of cotton which was of moment, but the ratio between the price of cotton and that of other market crops. The prices of other crops also were now up—sugar, for instance, and how about indigo where cotton came in conflict with that? He also thought that the cotton maps of India which were published gave a false idea of the possibilities of India as a cotton producing country. He had seen maps which showed cotton growing in the rice fields of Bengal; whereas the truth was that, on the whole, the cotton tracts were well defined and were almost all found in the western half of the country. Great progress had been made in increasing the yield of cotton per acre, especially in the Central Provinces, where a heavy yielding short staple variety had been found to give 110 per cent. more yield than that of a long staple kind which was first tried to be encouraged. The hope and ultimate aim would seem to be to establish definite types of cotton in definite areas of India; but to succeed in this they needed all the assistance and understanding possible from the trade. How potent such aid could be was suggested in Professor Todd's paper. If the agreement now come to in South Madras could hold for another year, more would probably have been achieved in two years for the purity and quality of Tinnevelly cotton than was likely to have been done in eight. Cotton also was not the only

crop in India. If anything, possibly a disproportionate amount of attention had been given to it. In five provinces of British India 98 per cent. of the total area under cotton in British India was to be found, yet in those provinces cotton only represented 9 per cent. of the total area annually cropped. There were also oilseeds and jute to demand attention. And above all there was rice, which it should be remembered was the staple food for the greater part of the human race. He believed that both the quality and quantity of cotton produced in India could be increased; but most of the labour fell on the Agricultural and Co-operative Departments, and to cope with cotton and all the other crops satisfactorily they need to be very greatly strengthened. He would ask those spinners who were interested in Indian cotton to come to India and see the conditions there, and give them the benefit of their advice.

Mr. N. N. Wadia said the previous speakers had based their views on the importance of speedily increasing the growth of Indian cotton. He, as a spinner and manufacturer in Bombay, could speak on this matter from an entirely different point of view; but at the outset agreed that it was possible, with Government help, materially to increase within a reasonable time the growth of long-staple cotton in India. One of the first things to bring about this result was a considerable increase in the staff of the Agricultural Department in India. The amount of money spent on the Agricultural Department was Rs. 370,000, or less than 5 per cent. of that spent in America. The Agricultural Department was mostly staffed by members of the Indian Civil Service and not by agriculturists who have devoted their lives to agriculture pure and simple. In his opinion, therefore, it was necessary that under the heads of the Indian Agricultural Department, who might be men from the Indian Civil Service, a special staff of trained agriculturists from America, especially those who had made a lifelong study of cotton-growing, should be provided in each Presidency. The next point he wished to make was the method to be pursued by this Department. The Agricultural Department always complained that they did not receive adequate encouragement from the Indian millowners, and they had experienced considerable difficulty in marketing the cotton grown under their supervision. Some of the other millowners arranged with the Bombay Presidency and the Agricultural Department to establish a buying agency in Sind. This syndicate of millowners were requested by the Bombay Agricultural Department to erect ginneries for ginning, pressing and marketing the American cotton grown under the supervision of that Department in Sind, and also keeping the seed separate, one at Mirkhaphus and the other at Shikarpur. One of the main conditions made at the time of this arrangement was that the Agricultural Department would grow about 200 to 250 bales at each of the above places in the year and bring their production at both these places within three years to about 2,000 bales a year, so as to make the ginneries pay their way. They would be surprised to hear that this condition was never carried out, that at Shikarpur in the last five years only 100 bales had been grown, and the ginning factory established there had never been worked, although that factory was erected at the request of the Agricultural Department at a place selected by that Department. At Mirkhaphus this year's crop, after five years, had only reached 250 bales. Under such circumstances they would see that no buying agency could pay its way. Professor Todd had laid great stress on the prevention of mixing of different varieties of cotton, and for that purpose licensing ginneries by legislation. He agreed that this prevention of mixing could only be effected if Government would legislate in the matter. He, for the last twenty years or more, as a weaver bought cotton in the Nizam States, and he could say from his experience that in that district the staple of the cotton due to mixing of seed had materially deteriorated during the last ten years, and the cotton he used to buy there having a staple of nearly an inch was now less than five-eighths of an inch, and it was getting worthless for purposes of weaving. In his opinion also, if damping by legislation was stopped, it would materially prevent the mixing of cotton by agriculturists. He repeated that if the Agricultural Department was staffed by a proper number of trained agriculturists, not only good staple could be grown, but the quantity could be materially increased, and he did not see why in the next ten years we could not look forward to having a million bales more of good staple cotton from India. In conclusion, Mr. Wadia drew attention to the fact that Japan was to-day importing cotton from Bombay at very little over the pre-war rate of freight. She was also importing cotton from America at practically pre-war rates of freight. British spinners were handicapped by the high rates of freight they had to pay for cotton imported by them either from America or India. With this advantage of freight, therefore, Japan was placing in the Indian markets woven goods in competition with Lancashire mills, and it was necessary for Lancashire mills to face this competition, which would grow more and more in the near future.

Mr. Augustus L. Beaufort mentioned a few statistics to support his view that he did not see any possibility of increasing the crop of India by one million bales per annum. During the last fifty years, starting with the five years ending 1867–68, India produced a little over tw

million bales. At the end of twenty-five years it had risen to $2\frac{3}{4}$ millions, and in the next series of five years it had risen to $3\frac{1}{4}$ millions. In the five years ending 1902-3 it was $3\frac{3}{4}$ millions; in the following five years $4\frac{1}{2}$ millions; and in the five years ending 1912-13 it was just under 5 millions. These were his own estimates, but the Government estimates were considerably less. In fact, his own figures were about 30 per cent. increase on the Government returns. In 1913-14 the crop was estimated by the Government at just over 5 million bales, including one million taken for local consumption, but he made it $6\frac{3}{4}$ millions. In the last two seasons the crop had been about $5\frac{1}{2}$ million bales, and he did not see, having regard to the slow and steady increase he had shown, that there was any possibility of getting another million bales annually. They had been told that in the Punjab the possibilities were very great, and that would be the only possibility of getting this large quantity if it were to be obtained. As to the quantity taken by Great Britain, at the beginning of the last half century we took $1\frac{1}{4}$ millions of the $1\frac{3}{4}$ million bales shipped. That total had dropped, until in the last five years of the half century we only took 98,000 bales out of 2,150,000 exported. Lancashire was always calling out for India to increase her cotton supply, but she steadily kept away from it. As a matter of fact, Indian cotton was going in increasing quantities to Japan. At the beginning of the half century the Far East took 74,000 bales, but at the end of it Japan took nearly two million bales, and in the last season 1,900,000. The Continent took 100,000 bales in the early sixties, and in the year 1913-14 nearly two million bales; whereas the exports to the United Kingdom were 166,000 bales. The total home consumption at the beginning of the half century was 665,000 bales, and of that about 600,000 bales were taken for local consumption other than by the mills. That figure was on the authority of Mr. Rivett-Carnac, who was Cotton Commissioner of the Central Provinces and Berar fifty years ago. In an examination of the area under cotton in the twenty-five years ending 1914-15, he found that the mean of the first five years was 15,541,000 acres, and in the last five 23,142,000 acres; the respective yields, according to Government, being 2,400,000 and 4,405,000 bales of 400 lb. That showed an *annual* increase of 300,000 acres and 80,000 bales. To meet the proposal of Professor Todd an annual increase of at least five million acres would be required, assuming an average yield of 80 lb. per acre. In the same quarter of a century the mean quinquennial area in the Punjab had risen from 795,000 to 1,690,000 acres, and the outturn improved from 168,000 to 404,000 bales, equal to 894,000 acres and 235,000 bales, the mean annual increases being 36,000 acres and 9,500 bales.

MR. SHAPURJEE SAKLATWALLA said he also would be somewhat detached from the views of the previous speakers, as well as perhaps from those of the reader of the paper. India, from the cotton point of view, had too long been looked upon as the kitchen garden of Lancashire, and he objected to such a narrow point of view. A similarly narrow point of view had been taken by the author and other speakers in regard to the possibility of an increase in the cultivation of cotton in India. One of the reasons for the success of America in cotton-growing was that the agriculturists there were very intelligent and highly educated, and the difficulty was that India should be always looked upon as a land of plentiful and cheap labour. The labour problem of India should not be looked upon in that spirit. Some day the Indian agriculturists would have to have the same educational facilities as the American, and then when the Indian agriculturists were better educated, and paid wages perhaps ten times those they now received, they would give more intelligent interest to the needs of the country and the Empire than was the case at present. An important factor in this connection was the fact that at present the Agricultural Department in India was so aloof from the daily life of the industry and did not reap the benefit from, on the one hand, nor did it give the benefit to, on the other, the industry which it was supposed to. He agreed with Mr. Wadia that it was necessary to place the Indian Agricultural Department in the hands of agricultural experts. When this was done, and efforts made to improve and make happier the lot of the Indian agriculturist, the results would be seen in the quality as well as in the quantity of the output. He further pointed out that Indian merchants and City men failed to recognise that agriculture and agriculturists needed to be organised and wisely directed. For any small factory there were technical supervisors and a board of merchant directors, but the immense mass of illiterate agriculturists were left to their fate without direction.

SIR CHARLES S. BAYLEY, G.C.I.E., K.C.S.I., briefly proposed a vote of thanks to the author for his paper.

MR. B. ABDY COLLINS, I.C.S., in seconding, mentioned that whereas the author had suggested an expenditure of about £10,000,000 per annum upon cotton-growing in India, the Government at present spent about £500,000 on agriculture altogether. If the paper and discussion led only to the doubling of that sum a very great service would have been done to India.

The vote of thanks having been carried, PROFESSOR TODD, owing to shortness of time, said he would send his reply in writing to the *Journal*

In reply to the discussion, PROFESSOR TODD writes:—In answer to Lord Emmott's point as to cotton taking its character from the soil and climate, there is, of course, a great deal in this, but I believe that in many cases the resources of Mendelian breeding have not yet been exhausted, and it ought to be possible to produce cottons suitable for each different set of conditions which will be at least much better in quality than the varieties commonly in use. But to do so attention must be paid to *all* the factors in the value of a cotton, and not so entirely to the question of ginning outturn, as seems to be the rule to-day in many parts of India. It seems paradoxical that India, which has the smallest yield of seed cotton per acre in the world, should pay so much attention to the question of the yield of lint per boll. In answer to Mr. Chadwick, what the world wants is, of course, a million bales of about an inch staple, but if it cannot get that immediately, to add ⅛ in. to the staple of a million bales of short staple cotton is the next best thing. An additional million bales of any kind of cotton is always of use somewhere, and helps to relieve the pressure everywhere. It is true that other qualities besides staple, *e.g.* colour, "twist," strength and the "character" of the cotton, are important factors in its value, but in the cotton trade, as a whole, and especially in Lancashire, length of staple is the prime factor, while regularity of staple probably comes next. Mixing of staples of different length can never be profitable. Yet I have been told in the Punjab that it is the trade in Bombay who want it mixed. You should have heard the derision with which that statement was greeted when I repeated it in Bombay. It is literally true in India that one half of the cotton world does not know how the other half live nor what they want. Sir Louis Dane's remark about damping shows the vicious circle with regard to such practices. Because one section of the trade is making a profit at the expense of another that other introduces a countervailing practice which is frankly fraudulent in the degree to which it is carried. Incidentally the same trouble exists in America with regard to Texas cotton, which is picked very dry, and afterwards gains weight when exported. There is nothing I personally regret more than the comparative failure of the Sind buying agencies, referred to by Mr. Wadia, which has been largely due to mutual misunderstanding, but I hope success will still be achieved in Sind. I hope that when Mr. Saklatwalla reads the paper he will find that he was quite in error as to my attitude with regard to the Indian cultivator. It is a mistake to suppose that the average negro cultivator in America is either very intelligent or highly educated. In neither of these respects are his attainments proportionate to his remuneration to-day.

DR. THOMAS SUMMERS, C.I.E., writes:—The greater part of Sind has been proved to be fit for growing cotton, and it is probable that a million bales would soon be produced from the two to three million acres which would be put under cotton when water is provided. Mr. G. S. Henderson, while Deputy Director of Agriculture in Sind, in comparing Sind with Egypt, wrote: "Both the Indus and the Nile deltas have been formed by the natural deposition of silt through countless centuries. They consequently have practically inexhaustible soil, if only a proper system of cultivation is provided." Mr. F. Fletcher, another well-known cotton expert, who was also in Sind for some years, stated: "If the whole of Sind were put under perennial irrigation, the potentialities of the province for cotton-growing could not be surpassed even by the United States, and the annual value of the agricultural products of the country would amount to not less than twenty crores" (£13,000,000). Mr. Fletcher's estimate was looked upon as too optimistic, but it is not impossible; and I am convinced that, in Sind, Government possess the best and most economical field for the extension of cotton-growing in India, if not in the British Empire. If only a beginning is made, before long the "Cinderella Province" will be transformed into the "Garden of India" as predicted by Sir Colin Scott Moncrieff. This can be done at comparatively small cost by diverting on to the thirsty land some of the water from the Indus, which now flows uselessly through the centre of the province into the sea. As the supply in the Indus is sufficient to irrigate more than twenty million acres, there is no question of deficiency of water, which sometimes hampers irrigation schemes in other parts of India. Sind's greatest scheme—the Rohri Canal, which can be begun as soon as the war is over—will be the greatest canal in India. It will open up a million acres of good cotton land in five years, and two million acres in ten years, and the value of one year's crops is estimated at more than the cost of the canal. This great canal has been strongly advocated during the last sixty years by Colonel Fife, who was the first to propose perennial canals for Sind, by Mr. R. B. Joyner, C.I.E., and by other Sind engineers; also by Lord Reay, while Governor of Bombay, and by several Commissioners in Sind, beginning with Sir Bartle Frere, and ending with Mr. A. D. Younghusband, C.S.I., and Mr. W. H. Lucas, C.S.I.

SHANGTUNG HOG-BRISTLE TRADE.

The following account of the bristle trade in Tsingtau, contained in a Japanese Government report, has been sent to his Government by the United States Consul at Tsingtau. Shantung Province, in which Tsingtau is situated, exports about 500,000 lb. of bristles annually. They are produced throughout the province, but especially well-known places of

origin are Weihsien, Taian, Laifu, Chinchou, Shaho, Pingtu, Tsinau, Chinchiakou, and Sochen. Although a few white hogs are found near Kiaochow and Tsimo, in this province, almost all of the remainder are black. The only bristles exported are the long stiff ones found on the back and sides of the hog, while the short soft hairs are used by the natives as fertiliser or for making ropes.

After being scraped off, bristles are combed to remove impurities, etc., and are sorted into bundles about 1½ in. in diameter, containing bristles of uniform length. This work is done principally by Chinese women earning about 2*d*. a day.

Bristles are judged as to length, thickness, lustre, stiffness, and admixture of foreign matters, and are graded into lengths, varying by quarter inches, from 2 in. to 6 in.; but in Shantung the lengths 2¼ in. and 5¾ in. are not sorted separately. Bristles that are long, thick, stiff, bright, and clean fetch the highest prices. Practically all the bristles in Shantung are brought to the vicinity of Weihsien to be prepared for shipment to the point of export.

The shops near Weihsien send buyers to all parts of the Province of Shantung to collect bristles, for which they pay from 3*d*. to 2*s*. 6*d*. per lb., unsorted, the average price being about 2*s*. Most hogs are slaughtered from October to March, and bristles are exported in greatest quantities in March and April.

While the different length of bristles may be bought as desired, they are commonly combined in fixed proportions, a certain quantity of each length being included in each assortment.

Bristles have hitherto been exported mostly to Germany, Great Britain, the United States, and France. The largest exporting firms have been all European—five German, two French, and one British. Sometimes these firms send compradores (native managers) to the Weihsien district to deal directly with the shops; but by far the greater part of the purchasing is done through Chinese brokers in Tsingtau. The latter do a brokerage business only and charge 2 per cent. The compradore receives the same commission. Five per cent. of the price is paid when the contract is made, and the balance on delivery of the goods. Charges on goods, *i.e.* freight, packing, etc., amount to about 12*s*. per 100 lb. between Weihsien and Kobe (Japan). The foreign firms, on receiving bristles from the interior, wrap them in paper bearing their own trade-marks, and pack them in camphor in matting-lined boxes.

All of the European firms except the British have ceased doing business in bristles in Tsingtau since the military operations took place. Consequently, dealers are shipping more through Tientsin. The amount shipped from Tsingtau in 1915 was less than half of that shipped in 1913.

It is estimated that there are 800,000 grown hogs in Shantung Province, and that 600,000 are slaughtered annually. Since each hog yields about 1¾ lb. of bristles, the export is only about two-thirds of the production. Large quantities of bristles are shipped from the neighbouring Province of Honan by railway to Tientsin. When the Shantung Railway is extended, in a short time, toward the west, this trade can be diverted to Tsingtau, and the future of the business seems bright.

EXPERIMENTS WITH BRINES IN SEARCH FOR POTASH.

Several deep holes have been sunk in the deserts of Nevada, and one is being drilled in Texas, under the supervision of the United States Geological Survey, in the search for potash. The Survey is also making some laboratory experiments designed to aid in discovering a cheap process of separating potassium salts from natural brines.

Since the importation of potash salts from Germany was stopped, the urgent need of a domestic supply has greatly increased, and the price of high-grade potash has advanced from £8 to about £100 a ton. Efforts to find commercially workable deposits in the United States have been eagerly and diligently made, both by private capitalists and public agencies. The Survey has endeavoured both to find deposits of soluble potash salts and to discover practicable methods of extracting potash from rocks that carry relatively large proportions of potassium. Every clue that might yield valuable results has been followed up in a country-wide investigation, extending from New York to California.

In the laboratory experiments special attention has been given to the evaporation of brines rich in potassium. The results of some of the earlier work were published late in 1915. More recent experiments have been made with the natural brine from Searles Lake, California, which contains the equivalent of nearly 12 per cent. of potassium chloride in the solid salts. The results are given in a recent Survey publication, entitled "Evaporation of Brine from Searles Lake, Cal." This report shows the changes in the composition of the solution resulting from the evaporation of the brine, the composition of the crystals deposited from the hot solution during evaporation, and the composition of the crystals deposited when the solution was cooled. A copy of the report may be obtained free of charge by addressing the United States Geological Survey, Washington, D.C.

The data recorded indicate that carefully controlled fractional evaporation and crystallisation, possibly combined with other treatment, promise much as a means of obtaining potassium from

brines similar to that of Searles Lake. Further study of the behaviour of the constituents of the brine under varying conditions may be made.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Fast Colours.—Despite the shortage of dye-stuffs, a few British manufacturers have been able to produce with fair continuity coloured cottons in a limited range of shades warranted in fastness against washing and sunlight. They had access evidently to supplies of the "vat colours" manufactured from anthraquinone, and the source of these supplies has been somewhat of a mystery. The main source in former days was the Badische Company, which gave the name "indanthrene" to these useful colours, the fastest known dyes for cotton, and appreciably more permanent than such vat colours as are made from a base of indigo. It seems that in a small way these colours had been manufactured on Cheshire soil by the German company before the war. By February, 1915, indanthrene was being produced by the Morton Sundour Fabrics, Ltd., of Carlisle, for use upon their own curtains and cloths, and for the use of a few other textile manufacturing concerns. Messrs. Claus & Co., Ltd., of Clayton, Manchester, have produced, under the name "duranthrene," blues and olive, of which large quantities have been supplied. The chloranthrene blue of British Dyes, Ltd., is the same colour under a distinctive name. These advances have been made in the face of considerable difficulties, and the success of three firms in what had hitherto been a purely German domain is a sign of good augury. It was conceded by the enemy that England might make the common colours, but our colour-makers were not expected to master the production of indanthrene within ten years.

Scientific Aid.—Probably the greatest aid rendered by organised science to textile industry is that which is applied when things go wrong. The man of science is summoned to tell the man of practice why the results have not fallen out as they always did before, or to suggest how some desired end can be reached. The chemist succeeds at times and fails at others, but without his aid there are innumerable small operations which could not be repeated with certitude, and very many processes which could only be performed at more expense. This being so, it is not the wisest policy to claim for science discoveries that have certainly empirical origins. The mercerisation of cotton and the recovery of grease from soapy water are claimed in a recent pamphlet as results of the application of science to industry, but such pretensions weaken and obscure the real case. Textile industry owes remarkably little to science in the way of large discovery, but the debt to science in facilitating tasks already undertaken is greater than is generally realised or acknowledged. The story of what scientific help has actually achieved, together with specimens of the difficulties waiting to be solved, would not be less effective in opening the minds and purses of manufacturers than any cruder and less tenable claims.

Paper Uniforms.—It seems certain from samples received in this country that German troops in the field are wearing uniforms composed of 40 per cent. of twisted paper, 40 per cent. of cotton, and 20 per cent. of wool waste or shoddy. This composition is certainly not affected from choice, and no good result attended German efforts to market tweeds made of wool and paper some half-dozen years ago. Passable-looking suits can be made with woollen and paper yarns alternating two by two, although their tendency to crease in wear and lie heavy in the hollows of the figure is perceptible. Naturally, the fabric is not improved by wetting, and because water is fatal to it manufacturers hesitate to employ paper thread even for the backing of cheap carpets. These snatches of cloth are one proof of dire straits, and the significance of their use as army clothing is not lost upon the minds of wool manufacturers in this country. Want of wool is believed to be not the least of the influences depressing and embarrassing the enemy and tending to bring the war to a close.

Hand Weaving.—The hand loom has lingered on in the woollen mill as a convenience for weaving short pattern lengths, but even in that capacity it is being replaced by fast power looms. It may be long before the hand loom disappears from the factory, for in rare cases even the hand mule survives, and serves the purpose of spinning trial lengths of yarn. The gradual disappearance is noted, however, by greybeards who worked at the domestic loom in their youth, and carried the raw and woven materials to and from the factory. The time lost in conveyance is one of the matters especially remembered, and there is no reason to doubt that this inconvenience was a prime cause of the concentration of looms in factories where they could be run by power at a speed which was not initially much higher than that of expert hand weaving. The change is not very sentimentally regarded by the craftsmen, and it is noteworthy that some of them dispute the idea that hand work is any better than power weaving. It is agreed that in general respects hand work is no worse, and that it permits of a more rigorous scrutiny of materials; but the theory that hand work is less mechanical than the crank-driven loom receives little support from experience. There are men, apprenticed to the hand loom, who are disposed to champion

machine work against all comers, and to make light of the factor of individuality that personal effort is supposed to bestow. A certain individuality of rhythm of movement is admitted, and bodies of hand-loom weavers working together come to identify particular weavers by the sound of their looms, exactly as one recognises footsteps; but it is even vehemently denied that personal characteristics—at any rate, of a beneficial kind—are transmitted to the woven cloth.

Flannel.—An American Court has laid down a definition of flannel which in at least two particulars varies from English understanding. It gives somewhat of a shock to hear that flannel is primarily "a woven men's wear suiting fabric." Flannel suits, dyed and undyed, plain or fancy-woven, are indeed known, but their flannel does not represent the original article as worn in infancy or as a garment next the skin. The definition continues: "consisting of carded soft stock wholly or largely of wool rather loosely woven . . . sold practically in the texture in which it leaves the loom." On this point suffice it to say that English drapers have been successfully pursued under the Merchandise Marks Act for labelling as flannel cloths not all-wool; but in other respects the definition may stand. The New English Dictionary notes, but does not unreservedly accept, the etymology which traces "flannel" to (Welsh) *gwlân*, wool. At any rate, the Welsh flannels are woollen, and the name is associated with Wales in the English mind. Certain "yerdes of fflanell" at one shilling the yard figured in the effects of Princess Elizabeth of York in 1503. A statute of 1606 relative to the true making of woollen cloths points clearly to flannels as articles in which "floxe, thrumes or Lambes wool" might be permitted. "Flannell Wadnall and Coverlets or Blanketts" might be made "in such sort as has heretofore been lawfully used and accustomed." Wadnalls are not familiar articles in these times, but their name may be thought to betoken some ancestor of the stuffed quilt.

Russian Trade.—Many eyes turn towards Russia in the expectation of large business after the war, and regret is expressed over the temporary difficulties of transport which limit and even forbid shipment of yarns and cloths at present. Russia has a considerable textile industry of her own, but according to recent advices 60 per cent. of the cottons and 75 per cent. of the woollens currently produced are consumed by the Central Government, the municipalities and zemstvos, and their hospitals. Stocks of goods are lower than was ever known, and money is more plentiful among the peasantry than at any earlier period. The mills in Poland, now occupied by the enemy, had a large trade with Russia, and their defection contributes to the shortage of supplies. An emissary of an American manufacturers' organisation reports that in 1912 there were 261 textile industrial companies in Russia, but much larger numbers of mill premises are recorded in the factory inspection returns.

GENERAL NOTES.

Bauxite Deposits in France.—In an article entitled "Un Grand Marché Français à reprendre aux Allemands," which recently appeared in a Nice journal, *L'Eclaireur*, mention was made of the important deposits of bauxite at Luc, in the Department of the Var, about 75 miles from Nice on the main line of railway to Marseilles. The ore, which is of a reddish colour, due to the presence of iron oxide, contains a large percentage of oxide of alumina. Before the war the whole output of mineral from these workings, which was considerable, was chiefly sent to St. Maxime, a little port on the Gulf of St. Tropez, and also to Nice or Toulon, for shipment to Germany, where the aluminium was extracted and returned to France in the manufactured state. It is to be hoped that after the war this practice will no longer obtain, and that kitchen utensils, and other articles of aluminium, "made in Germany" will no longer flood the home markets. Surely, with the unlimited water-power available, or *houille blanche* ("white coal" as it is fancifully called), the mineral resources of the district could be profitably utilised by modern electrical processes of extraction. Other deposits of this mineral are to be found in the South of France, notably those at Baux (hence the name "bauxite"), in the Department of the Bouche du Rhône. These mines are situated on the southern slopes of a range of hills called "La Chaîne des Alpines," about ten miles north-east from Arles and a short distance south of the village and railway station of St. Rémy.

Tobacco in Ontario.—About seven million pounds of tobacco is now being grown annually in Ontario, and the rapid expansion of the industry during the last few years has, according to *United Empire*, necessitated the appointment, by the Dominion Experimental Farms Tobacco Division, of three experts from the tobacco belt of the United States. One is to take charge of the laboratory at Ottawa; a second is charged with the investigation of the tobacco soils of the various districts, and with problems of culture, fertilisation, and curing of the tobacco crop; and a third with investigations regarding the varieties best suited to the Canadian climate and market, the best methods of handling the crop under existing conditions, and all problems connected with the production of tobacco. The assistance of these experts will be available to any farmer.

Journal of the Royal Society of Arts.

No. 3,346. VOL. LXV.

FRIDAY, JANUARY 5, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 10th, 3 p.m. (Juvenile Lecture.) Mr. ALAN A. CAMPBELL SWINTON, F.R.S., "Electricity and its Applications." (Lecture II.)

The lecture will be fully illustrated with numerous experiments.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

JUVENILE LECTURES.

On Wednesday afternoon, January 3rd, Mr. Alan A. Campbell Swinton, F.R.S., delivered the first lecture of his course on "Electricity and its Applications."

The lecturer began by remarking that electrical phenomena had been observed as long ago as 600 B.C., when Thales of Miletus noted the electrical properties of amber; while Pliny, in A.D. 60, recorded that jet possessed similar properties. Gilbert, physician to Queen Elizabeth, discovered other substances with these qualities in addition to amber and jet, and in 1647 Otto von Guericke of Magdeburg invented his well-known frictional electric machine in which he used sulphur. A picture of the apparatus was shown on the screen.

An interesting story was related showing one of the preliminary steps to the discovery of the Leyden jar. Cuneus of Leyden was trying to electrify some water in a bottle. For this purpose he held the bottle in one hand, his hand thus forming an outer coating to it. He had previously placed in the bottle a nail connected with the electrical machine. When he thought the water was sufficiently electrified, he endeavoured, with the disengaged hand, to remove the nail. The result surprised him, and Muschen Broek, his master, on repeating the experiment, received so great a shock that he lost consciousness, and was so frightened that he afterwards wrote that for nothing in the world, not even for the crown of France, would he go through it again. Happily, other physicists were less fearful, and continued to work at the experiment which ultimately led to the modern Leyden jar.

Having briefly referred to the parts played by Franklin, Volta, Galvani, and others in the development of electrical science, Mr. Campbell Swinton proceeded to give a series of interesting and beautiful experiments. He showed the process of decomposition of water, electroplated silver and copper coins, and repeated the experiments of Faraday which led to the evolution of the dynamo. Among some remarkable photographs thrown upon the screen were two taken by Professor Boys: the first was of an electric spark, showing that its duration was about $\frac{1}{1,000,000}$th of a second, and the other of a bullet travelling at 2,040 feet per second, taken by the flash of an electric spark.

The concluding series of experiments dealt with the phenomena of high-frequency induction. Disconnected electric lamps were lighted; a gas jet was kindled from the lecturer's finger; the power of induction between large hoops of copper was demonstrated; and, finally, some beautiful illustrations were shown of the remarkable colour effects seen in the spiral-wound vacuum tube.

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

COAL AND ITS ECONOMIC UTILISATION.

By John S. S. Brame,
Professor of Chemistry, Royal Naval College, Greenwich.

Lecture I.—Delivered November 27th, 1916.

The economic importance of coal we perhaps hardly realise. It is the only raw material we produce in great quantity; the value of our total mineral output in 1913 was over £160,000,000; of this the value of the coal at the mine was over £145,500,000. Next in importance came iron ore, but the quantity produced was only one-eighteenth that of coal, its value but little over £4,500,000.

The great value of coal to us lies in its universal application—for power production, for metallurgical purposes, for providing us with heat and light, for furnishing as by-products in its distillation some of the most valuable materials in the realm of chemical products.

On coal the industrial greatness of Great Britain has been built up. On coal we must depend for the maintenance of our industrial supremacy. The use of coke for smelting our iron ores gave the first big impetus to the increasing production of coal. Cheap coal meant cheap iron and steel. From cheap iron and steel we may trace the development of our big engineering output, and, when iron and steel replaced wood, of our immense mercantile marine. Coal provided the source of power for driving the machines we made by the use of coal, and gave rise to the great textile and other industrial concerns which have made us one of the greatest and richest manufacturing nations.

No less true is it that coal has been the important factor in the development of that great Navy on which to-day we place our reliance. By the aid of coal we have produced our iron and built our ships and guns, and, though oil fuel plays no small part in driving them, still our smokeless Welsh coal is perhaps as valuable an asset to us as ever.

In the arts of peace coal is invaluable to us; no less valuable is it to us in the science of war. Coal may truly be termed *the* munition of war. I cannot bring before you its importance in words of my own which are half so forceful as an utterance of Mr. Lloyd George in the early part of the war:—

"In times of peace coal is the most important element in the industrial life of the country. In peace and in war King Coal is the paramount lord of industry. It enters into every article of consumption and utility. It is our real international coinage. We buy goods abroad—food and raw material. We pay, not in gold, but in coal. In war it is life for us and death for our foes. It not merely fetches and carries for us, it makes the material and the machinery which it transports. It bends, it moulds, it fills the weapons of war. Steam means coal. Machine-guns mean coal. Cannons mean coal. Shells are made with coal. Shells are filled with coal. The very explosive inside them is coal, and then coal carries them on right into the battlefield to help our men. Coal is everything to us, and we want more of it to win victory. Coal is the most terrible of enemies and it is the most potent of friends."

To quote Mr. Asquith: "The importance of coal in the great national and international struggle in which we are engaged is only exceeded by the importance of men."

Not only is coal of importance to us as furnishing the fuel for the production of iron and steel, for providing the power to drive our great factories busily engaged in the production of munitions, for providing power for our Navy and great fleet of transports, but the by-products from its distillation form the raw material for our high explosives, for the purpose of defeating our enemies; for many valuable preparations for the treatment and alleviation of the sufferings of our wounded; for disinfectants, for photographic materials, and other purposes directly connected with the war.

Coal, indeed, may be regarded as the black diamond without which the silver bullet is useless.

One of the most urgent problems of the war has been the maintenance of the output, in the face of difficulties arising from reduction of labour. Up to the end of June, 285,000 miners had joined the colours. At the present time there is a shortage of 153,000 men, or 14 per cent. of the normal number engaged in coal-mining.

But in these lectures we are more specially concerned with the future. We all realise that our stocks of coal are not inexhaustible, that our consumption has gone up by leaps and bounds, that we have been shockingly improvident in the production and use of this invaluable mineral. The movement for economy which is now being energetically conducted is no new movement; many eminent men have appealed for economy, and up to the present largely in vain. Professor Jevons' book on the coal

question, published in 1863, led to the appointment of the first Royal Commission, which published a report in 1871. More recently we have had the report of the second Commission (1905).

Among the eminent men who have tried to force the question on the attention of the nation was the late Sir William Ramsay, who made it the subject of his Presidential Address to the British Association. Again, at the fourth annual meeting of the British Science Guild, he drew attention to "the waste of the natural sources of energy of the Empire," and a committee afterwards furnished a valuable report on the subject.

I fear, however, that much of what was done in the past was in the nature of appealing to the converted—a small, if select, audience. Better fortune may befall the movement which has been so energetically started since the war, largely by Professors H. E. Armstrong and W. A. Bone. In his characteristic trenchant manner, Professor Armstrong has endeavoured to galvanise the industrial chemists into action, as being those having the knowledge which carries with it the right to demand Government action. His recent constructive addresses to sections of the Society of Chemical Industry are worthy of most careful study. Before the Newcastle Section his thesis was on "The problems of coal with reference to the complete and provident utilisation of the supplies and of fuels generally: a preliminary discussion and scheme" (*Jour. Soc. Chem. Ind.*, 1916, 35. 220). At the annual meeting last July, Professor Armstrong laid before the Society further views on the question under the title "Fuel Economy: a national policy required" (*Jour. Soc. Chem. Ind.*, 1916, 35. 765).

Professor W. A. Bone has also been most energetic in pushing this truly "burning" question. In addition to initiating a valuable discussion before the London Section of the Society of Chemical Industry (*Jour. Soc. Chem. Ind.*, 1916, 35. 389) and the Nottingham Section (*loc. cit.* 674), he has delivered himself more fully at the Royal Institution. Through his energetic action the British Association was led to appoint a Committee on Fuel Economy, which includes many men particularly well able to deal with the problems set aside for the consideration of the various sub-committees on which they serve. These are: (*a*) Chemical and statistical; (*b*) carbonisation; (*c*) metallurgical, ceramic and refractory materials; (*d*) power and steam raising; (*e*) domestic heating and smoke prevention. A preliminary report was furnished this year, and there can be no doubt that the information which the various sub-committees have set out to obtain will prove of the greatest value in paving the way for future action.

The first step towards the realisation of economy in the production and utilisation of coal is to convince the more thoughtful members of the community of the necessity. They must be taught that not only are enormous economies possible, but that economy *will pay*, in many cases quickly, in every case before the lapse of many years.

The improvident use we have made of coal has been in great measure due to its cheapness. The great public has remained untouched by the appeals of scientists, who have addressed scientists already convinced. The war has brought the coal question home to the more thoughtful members of the community; the prominence which the by-products have assumed as raw materials has forced them to realise that coal is not something merely to be burnt.

Valuable as the results from the British Association Committee promise to be, and of the discussions before the Society of Chemical Industry and other societies, individually they cannot carry the weight which a united action on the part of the scientific and technical societies would. The Royal Society of Arts, with its traditions and with over a century and a half of useful work as an educational institution, should take a prominent place in this movement. It is because of the pressing importance of the coal question, and because I hope to see this Society lending the powerful weight of its educational advantages and its prestige to advancing the movement, to making it a problem to be dealt with and not shelved, that I have chosen this question for this course of lectures, in the hope that this Society may take action in conjunction with others.

Turning to our output of coal and our home consumption in the year 1913, a period undisturbed by domestic troubles or by the war, we touched high-water mark in production, and in consumption, with an output of 287,430,000 tons, of which 189,000,000 tons were retained for home use. The number of employees was 1,110,884, which gave an output per head of 259 tons.

With the outbreak of war our production quickly fell off. The response of the miners to the country's call by joining the colours has been so splendid that in 1914 the output fell to

265½ million tons; in 1915 to 253 million tons. The demand for coal, however, increased with the enormous activity in the production of munitions, but the home consumption in 1914 was 184½ million tons, and about the same figure for 1915. It was therefore the export trade which suffered.

The industrial rise of Great Britain, as measured by the coal barometer, and also our export trade, may be seen from Fig. 1, showing the quinquennial output and export from 1871 to 1915:—

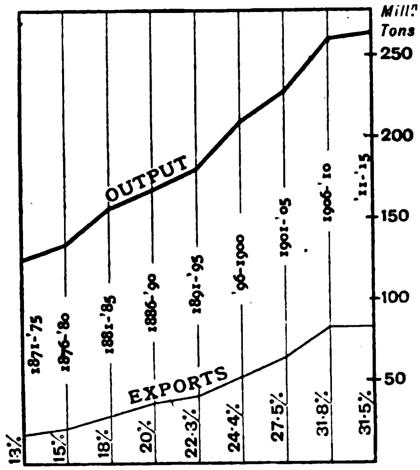

Fig. 1.—Production and Export of Coal, 1871-1915.

In the period of forty-two years, from 1873 to 1914, we have raised 8,206,243,000 tons, and exported 2,012,796,000 tons, or more than 24½ per cent. The value of the coal raised was equal to over 84 per cent. of the value of our whole mineral output.

But to grasp the importance of the coal problem, we must study it in relation to our greatest commercial rivals. In the middle of the last century, small though our output was in relation to the present output, it was by far the largest in the world. The United States and Germany have, however, increased their rate of production per annum at a much greater rate than we have; since 1876 the United States output has doubled itself in every twelve or thirteen years, until now it is nearly twice as great as our own. Germany has also gained rapidly upon us, her average output for the five years 1910–14 was practically the same as ours for the period 1886–1890.

The striking character of these developments in production in these three greatest coal-producing States will be seen from Fig. 2.

It is difficult to estimate the consumption of coal in the various industries; but the 1905 Commission published figures which they regarded as approximately correct for the year 1903, when the consumption was 167,000,000 tons. These figures may be brought up to date *pro rata* without serious error being involved, as the proportions will have altered to a less extent than the probable error in computation. Taking an average consumption just prior to the war of 187,000,000 tons, the figures are:—

	Million tons.
Railways (all purposes)	15·0
Coasting steamers (bunkers)	2·5
Factories	60·0
Mines	20·0
Iron and steel industries	31·0
Other metals and minerals	1·0
Brick works, potteries, glass works, chemical works	6·0
Gas works	16·5
Domestic	35·0
Total	187·0

Having considered our output and consumption the question arises naturally, what stocks have we, what inroads have we made on them, and how long will the stocks last?

The last is too highly speculative and has too little real bearing on the question of economy to justify more than a reference to the insuperable difficulties of making such an estimate. It rests on undeterminable factors, such as the probable rate of increase of consumption per head of population, the rate of increase of population, the possible decrease in our export trade as other countries develop their export trade—notably the United States. The effect which the great war will have on these factors, notably population twenty years hence for example, cannot be gauged.

Estimates of stock can, however, be made with some approximation. Both the 1871 and 1905 Commissions took 4,000 ft. as the limit of depth for workable coal. Deeper mines are known, but working expenses necessarily mount up rapidly as greater depths are reached. The shaft is more expensive and the cost of winding, roads are more difficult to keep open, the quantity of crushed coal is considerably increased.

The thickness of paying seams depends on a variety of factors. The Commission took a minimum of one foot. Then deduction must be made for coal which must be left as barriers, supporting pillars, etc. This is very variable in

different fields, but the average figure of 22·7 per cent. was adopted. On this basis the following estimate was made, the figures being in million tons :—

ESTIMATED COAL RESERVES, ROYAL COMMISSION, 1905.

	Not exceeding 4,000 ft.	From 4,000-10,000 ft.
Proved	100,914	5,239
Unproved	40,721	—
Totals	141,635	5,239

Certain important districts where coal was known to exist were not included, as the data were doubtful. These included Kent, and probable extensions of the Gloucester and Somerset fields and of the Cheshire basin.

A few words may prove of interest about the Kent field, which is of particular interest to us in London and of wider importance because of its geographical situation in relation to the North Sea and Channel.

Dr. Aubrey Strahan, of the Geological Survey, put down the probable reserves of Kent as 2,000 million tons, which Professor H. S. Jevons considers far too conservative an estimate. According to him, from borings which have gone to 2,500 ft., it is established that over an area of 150 square miles the total thickness of the seams (of 18 in. and over) is from 30 to 40 ft. If the area is no greater than this, and there is reason to believe it is much more extensive, the reserves would be some 6,000 million tons.

Much of the coal, however, is very soft; at least, this is so in the upper seams, so that the percentage of large coal is not high. At greater depths excellent hard coal is obtained. From

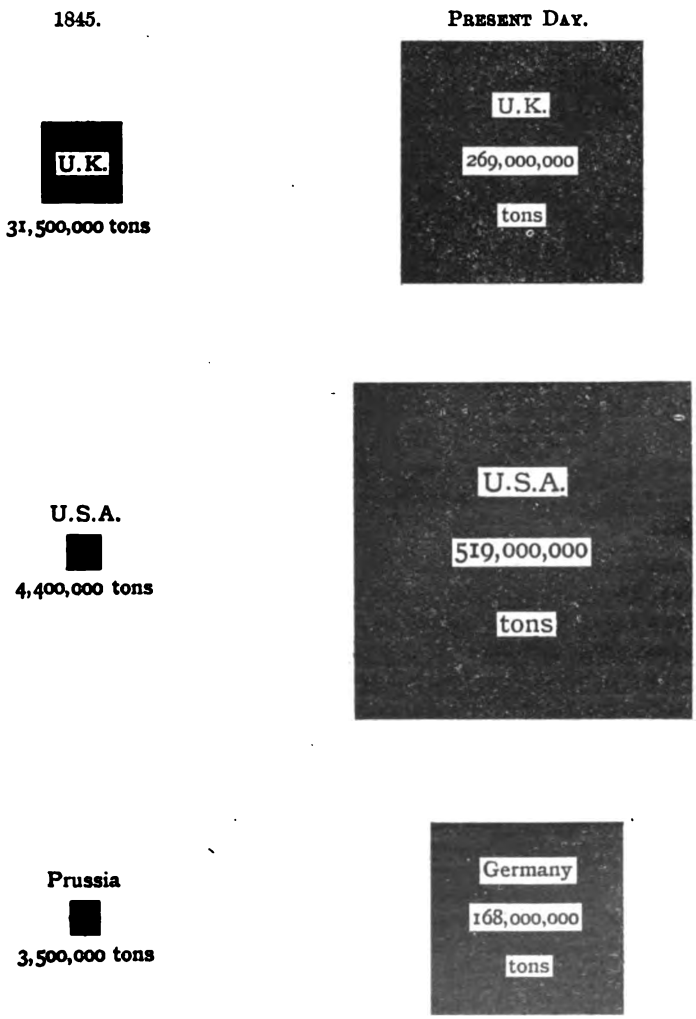

FIG. 2.—OUTPUT OF COAL, 1845 AND PRESENT DAY.

samples taken from borings it may be concluded that three distinct classes of coal are found, the average composition for the pure coal substance (*i.e.* free from ash and moisture) being as follows:—

Carbon.	Hydrogen.	Sulphur.	Nitrogen.	Oxygen.	Volatile constituents.
86·5	5·10	1·21	1·04	6·1	28·5
87·8	4·76	1·18	1·06	5·1	22·0
90·0	4·44	0·92	1·02	3·4	15·6

It may be noted that the composition of the last class is very close to the average composition of the high-class Welsh smokeless coals. If the burning qualities of the coal are as good, and the seams are workable, the occurrence of such coal so conveniently situated in relation to several important naval bases may prove a valuable asset to the Royal Navy, and the nation might well consider the question of reserving these beds, for, in spite of our extended use of oil fuel, smokeless coal is, and will continue, in great demand.

To return to the probable coal reserves of this country and Dr. Aubrey Strahan's estimates, we have the following:—

	Not exceeding 4,000 ft.	From 4,000 to 6,000 ft.
Actual reserves . .	133,117	6,108
Probable and possible	45,610	1,659
Totals . . .	178,727	7,767

I think it is safe to take the coal reserves not above 4,000 ft. deep at the round figure of 180,000 million tons.

Comparison may now be made between our reserves and those of other countries. For this purpose we may turn to the valuable statistics relating to the probable coal reserves of the world, compiled for the International Geological Congress held in Canada in 1913. The returns were made in metric tons, so that for a proper comparison with British official returns these have been converted to Imperial tons. The following figures are given for Europe:—

	Million tons.
Germany	415,794
United Kingdom	186,153
Russia	59,079
Austria-Hungary	58,211
France	16,270
Belgium	10,803
Other Countries	22,926

It will be seen that Germany possesses 54 per cent. of the whole; Great Britain, 24 per cent.; Russia and Austria-Hungary about 7·6 per cent. each; and France, 2·1 per cent.

But the coal reserves of Europe are only approximately one-seventh as great as those of North America, the bulk of which coal lies in the United States, although Canada is fortunate in having considerable supplies (over 1,100,000 million tons). The following table shows the estimated reserves of the world:—

ESTIMATED COAL RESERVES OF THE WORLD.

	Million tons.
North America	5,023,760
Asia	1,256,690
Europe	770,170
Australia	167,600
Africa	56,800

Of the world's probable reserves, then, North America can claim nearly 69 per cent., of which, approximately, 40 per cent. lies in the United States. Asia comes next with 17·3 per cent., leaving Europe a poor third with about 10·5 per cent.

We are now able to consider our position in relation to that of our nearest commercial rivals. Broadly, the manufacturing activity of the great nations may be gauged by their coal consumption. Taken in relation to their probable reserves, the output of the three largest coal-producing countries is as follows:—

	Output in million tons (1910-1914).	Probable reserve in million tons.	Percentage of output to reserves.
United States	519	4,000,000	0·013
Germany .	168	415,800	0·040
Great Britain	269	186,600	0·140

In round figures the percentage of the output which is retained for home consumption is:—

United States	over 90 per cent.
Germany	75 „
Great Britain	67 „

Not only are we exhausting our supplies at a far higher proportionate rate than our nearest commercial rivals, but we are retaining for our home use a much smaller proportion of the output.

It is not a question of the exhaustion of our coal supplies, but of the time when our easily and cheaply won coal has, to a large extent, been used up and coal is becoming relatively dearer in relation to other commodities and to the cost of production in rival countries. They

must also expect to meet with a rise in cost of production, but the greater the reserves in relation to the output, the further off is this period of marked rise of prices likely to be. More particularly should our position be considered in relation to the United States, beside whose reserves ours are relatively very small, and whose enormous deposits of iron ore place it in a most favourable position. Another factor which must react in favour of the United States, as compared with Europe is the effect of the war, which, whilst depleting the wealth and population of European countries, adds greatly to the comparative resources of the United States.

Already in this country the cost of coal has been rising very appreciably in the last few years; before the war period it was some 25 to 30 per cent. dearer at the pit than ten years previously. As the workings get deeper the cost of shafts, of winding, of maintenance of the roads, all increase. Wages are continually increasing, and legislative action, necessary for the safety of the miners, becomes more stringent and adds to the cost of production.

It is clear that if Great Britain is to maintain her place among the great nations she must remain a great manufacturing centre, and this depends entirely on cheap fuel. The necessity for economy in place of waste is apparent, and enormous economies are undoubtedly possible. The Royal Commission (1905), from figures supplied by Mr. Beilby, estimated that a possible saving of from 20 to 30 million tons might be effected in the consumption for power purposes alone. Quite a conservative estimate of savings which might reasonably be achieved would amount to 50 million tons annually. In production there is much inevitable waste, but there can be no question that very large quantities of coal might be saved by better methods of working and in preparation of the small coal for the market.

So closely, however, is the coal question interwoven with our industrial life, that it fairly bristles with economic difficulties. Following well-recognised trade laws, if economies in production and in use keep coal cheap, industries dependent on coal flourish and the demand for coal consequently increases. This, of course, indicates present prosperity, due directly to the avoidance of waste and so adds to the national wealth; but coal economists who look to avoidance of waste as contributing to the conservation of our stocks are apt to overlook this important compensating effect.

One very important and very difficult question is that of export. As has been shown, our export trade has rapidly increased until in the period just before the war we were sending out of the country one-third of our output. It cannot be denied that in our export trade we have, to a large extent, developed our industrial greatness. It has given us supplies of other raw material for our factories in exchange; it has determined largely the growth of our great mercantile marine. As Mr. Lloyd George said: "We buy goods abroad—food and raw material. We pay, not in gold, but in coal." To quote Mr. Asquith: "Coal is our chief and in many ways our most necessary export. It helps to feed the country by bringing in food from abroad. It helps to pay for the war. It assists, perhaps more than any other commodity, in keeping up the rate of exchange."

But we must look at this question of export on a wider front than the immediate present or the immediate future. It is perhaps not realised that in the last five years prior to the war we reduced our reserves through export by the equivalent of two years' consumption; that in the period of forty-two years—1873-1914—we exported in all 2,012,796,000 tons of coal. If, as our political economists tell us, our export is essential to our well-being, we must realise that it is at the cost of bringing the day rapidly nearer when industries will be hampered by dear coal—in other words, mortgaging the interests of posterity in the interests of the present, and possibly a few succeeding generations; and I doubt whether the blessings of posterity will fall on the economical system which permitted this.

One realises that this is a thorny subject; it is evident that no drastic interference with our export of coal is possible, but, as pointed out by the Royal Commission of 1871, "a time must be anticipated when it will be more economical to import part of our coal than to raise the whole of it from our residual beds, and before complete exhaustion is reached the importation of coal will become the rule and not the exception of our practice." Our plain duty is to consider this question very carefully in all its manifold ramifications in order that the evil day of importation may be postponed as long as possible. Certainly the export of this essential commodity which cannot be replaced, and for which no adequate substitute is likely to be found, should be made contributory to the provision of means for meeting the future requirements of the nation

and maintaining its prosperity when we cease through natural or other causes to be exporters.

The suggestion which has been made for the re-imposition of a duty on export coal, the proceeds from which should be applied to the investigation of our coals and the development of schemes for the more economical utilisation of the coal we consume, would appear very sound.

Exportation and the nationalisation of our coal supplies must become great issues to be decided some day. Sooner or later I feel convinced that a leaf will have to be taken from the book of the extreme Socialist, who wishes to tax large fortunes out of existence. Coal exports will be gradually taxed out of existence; but the process must be very gradual because of the dislocation of an economic system which has been the means of bringing great wealth to the nation, but of which wealth future generations will not inherit sufficient to compensate them for their loss of cheap fuel largely through our prodigious exports.

Again, coal is the principal natural wealth of the nation. Under our system it has been handed over to private interests to exploit in an unrestricted manner (except by legislation affecting the safety of the workers), and the nation has inalienable rights to demand that it shall not be recklessly expended or sold for gain (often to the great advantage of commercial rivals) without the nation profiting by the transaction in such a way that its future prosperity is, as far as possible, provided for in other ways.

The cheery optimist, however, does not worry over this question, even if he realises the grave issues involved. He relies on the scientist "discovering something" before our coal is running short, and so saves himself the trouble of considering the question. But what are the alternatives to coal, and what are the prospects of some great discovery? The British Science Guild published some careful considerations of the alternatives which might be open to us. Oil fuel is not produced throughout the whole world in sufficient quantity to furnish more than a fraction of the fuel required; moreover, it must always be an imported fuel in this country. In water-power we have no great possibilities; until some more efficient form of storing energy is available, the enormous resources in the winds are of no help. The great energy of the tides and waves would entail an enormous expenditure, and some very difficult practical problems would have to be solved. The enormous potential forces set free by atomic disintegration would, in the opinion of the late Sir William Ramsay, not be capable of replacing fuel or water-power—it could not pay. Underground heat, according to the Hon. R. J. Strutt, will not prove the solution. In fact, there is no alternative in sight, and we must rely on the utilisation of our coal in the most economical manner which scientists, engineers and manufacturers can devise.

Even if other sources than the above were available, we should not possess them in relative advantage to others; indeed, in many instances, we are distinctly at a disadvantage.

In discussion on coal economy I do not think sufficient weight is given to what has already been accomplished. We have indeed made very considerable progress, but that by no means implies that our efforts should relax. Rather does it emphasise the cases where improvident use of coal still continues, and point the way for fresh advances. Much more small coal is brought to bank, and rendered good serviceable coal by proper preparation for the market, or for use in coking plant. We have made substantial progress in the replacement of the wasteful beehive coke ovens by systems which are more economical and give us the benefit of the by-products; our gas producers have made considerable strides in producing gas with a much smaller works consumption of fuel, and in extending the use of gas and coke for industrial and domestic heating. In all our larger steam-power producing concerns, by the introduction of mechanical stoking, of water-tube boilers and notably of turbines, very considerable reduction in fuel consumption per unit of energy has been achieved. Lastly, the more general introduction of plants for gasifying coal and schemes for the utilisation of waste heat from coke ovens and blast furnaces have resulted in noteworthy economies in use.

The rise we have experienced, and the future enhanced cost of coal which we must expect, may prove the most important factor in promoting economy. Because coal has been cheap it has not paid to study economy.

Professors Armstrong and Bone have laid great emphasis on demanding Parliamentary action. But I believe it is to sound commercial enterprise that we must look for the greatest economies in the use of coal. Parliamentary action in this direction can only be indirect — in making provision for a national fuel-testing station, where large scale investigation on our different

coals and the most suitable ways of economically using them may be carried out; by financing research work in relation to the composition of coal, and the scientific principles involved in its application; and in general encouragement of technical education throughout the technical schools of the country on coal and fuel economics.

The nation certainly has the right to demand direct Parliamentary action for preventing wasteful methods of production; for dealing with coal left underground, either as necessary barriers, supports, etc., or because at present it is more remunerative to the owner to bring to bank only the best of the coal; for insisting on the working of thinner seams or poorer seams which have been left for similar reasons. But I do not believe Parliamentary action can ever be stimulated for such a scheme, as suggested by Professor Armstrong, as the prohibition of the use of raw coal for domestic purposes after a given time limit, or for the total prohibition of the use of raw coal for industrial purposes generally, as some enthusiasts have advocated.

On cheap coal England's commercial greatness has been built up; the day when coal in this country becomes relatively dear will mark the commencement of the restriction of some of our greatest industries, notably iron and steel. To maintain our position we must stave off this evil day; we must consider every means of economy in production and use. If necessary, and I think there can be no question of the necessity, we must gradually restrict our export of coal, and must rely upon something other than this export of the blood from the country's commercial arterial system for the maintenance of our foreign trade.

As Professor H. S. Jevons so aptly puts it, "Englishmen must take heed in the future to rely less upon exploiting our vast stores of national wealth, and more upon the resources which scientific skill and practical education can place at our disposal."

DEVELOPMENT OF THE KAMERUN.

Kamerun lies between British Nigeria and French Kongo, and extends from the coast northeastward to the southern shore of Lake Chad. In 1913 a considerable tract of land, extending south to the Kongo and Ubangi rivers, was transferred to Kamerun from French Kongo, the new acquisition being known as New Kamerun.

The colony covers an area of 305,140 square miles and, according to the latest estimate, has 2,720,000 inhabitants, of whom 1,550 are whites. Bantu negroes inhabit the coastal regions and Sudan negroes the interior.

The Colonial Government has opened to traffic 105 miles of the Northern Railway (3·28 ft. gauge), from Duala to Nkongsamba, and the central line from Duala to Edea, a distance of about fifty-six miles. A tramway is also in operation from Buea, the capital, to Victoria, the seaport, a distance of twenty miles.

As in many parts of West Africa, the richest natural resources of the colony are in the hinterland, and the lack of transportation facilities to the sea-coast has retarded its development.

It has been proposed gradually to extend the construction of the railway from Duala as far north as Parua, nearly 550 miles inland on the Benue River, so that it would tap all of the northern interior; the Duala-Edea line also was to have been continued to Widimenge on the Nyong River, about 130 miles beyond Edea. A railway from the port of Kampo, near the frontier of Spanish Rio Muni, into the hinterland has also been proposed.

Motor-car lines of more or less importance as transport mediums were established, the one from the port of Kribi to Jaunde, about 200 miles inland, being the most extensive. Considerable attention was given to road construction, with the result that in some parts of the colony good roads between trading posts are found. In the regions more distant from the larger towns, however, the only means of transport are still the caravans composed of native carriers. The chief rivers, the Sanaga, Munga, and Wuri, are navigable by steamers for a distance of thirty or forty miles; beyond that caravans must be employed. As the natives can only carry loads of 60 lb. or 70 lb. for a distance of twelve to fifteen miles per day, and as it takes thirty days to go from Duala to Middle Kamerun and twenty days to Lake Chad, it is evident that few products, except rubber and ivory, can bear this expensive means of transport.

During the first years of German occupation palm oil and kernels were Kamerun's chief products, the exports even exceeding those of rubber. Since 1902, however, rubber has taken predominance, and about one-half of the total exports are now comprised of this product, the value of shipments to Europe having advanced from £546,000 in 1912 to £577,000 in 1913.

According to a report by the United States Vice-Consul at Boma, Kongo, the first attempts at rubber exploitation were made in the northern part of the colony, where the *Landolphia florida*, which was then regarded as the greatest rubber-producing plant, was found. About 1901 the vast forests of Southern Kamerun were discovered to contain great numbers of "kickxia" trees, and the natives were soon set to gathering the "silk rubber" therefrom; but their methods were crude, and resulted in the destruction of so many trees that the move-

ment soon fell off. The rubber crisis of 1912 also caused a decrease in the wild-rubber trade, but at the same time it gave considerable impetus to the establishment of rubber plantations.

Realising that the "kickxia," one of the most valuable rubber plants, was indigenous to Kamerun, the German planters commenced to cultivate it about four or five years ago, and now there are many plantations containing thousands of trees that will soon begin to produce large quantities of first-quality plantation rubber.

The estimates as to cost of production on these plantations compare favourably with those of the Brazilian and East Indian rubber companies. The trees are planted on cleared jungle and brush land and the initial costs are thus small, the average expenses for planting (including labour, implements, etc.), being about £10 per acre. The cost of the upkeep of planted areas is calculated at about 30*s*. per acre for the first year, 22*s*. for the second, 18*s*. for the third, and 10*s*. for the fourth. The trees begin to bear during the fifth year, and it is said that over 1½ lb. of dry rubber may be obtained from a six-year-old "kickxia" tree. The cost of tapping the trees and shipping the product to Europe should not exceed 1*s*. 3*d*. per pound, and, if properly prepared, it is thought that the Kamerun plantation rubber will fetch about the same price as the best Para rubber in European markets. Native labour is fairly plentiful in the rubber-growing districts and costs, including board, about £1 per month. It is likely, therefore, that rubber will remain the most important product of Kamerun for many years.

The gathering of palm kernels and the extraction of the oil therefrom are still important industries of Kamerun. The value of the exports of kernels increased from £210,000 in 1912 to £296,000 in 1913, and of palm oil from £77,000 to £93,000. The trade in palm products is second in importance to that of rubber as to the value of exports. The oil is extracted almost entirely by the natives, whose methods are crude and result in considerable waste. The installation of machinery would add greatly to the importance of the industry.

The cultivation of cacao has attained considerable importance in Kamerun within a very short time. As climatic conditions are similar to those of the Island of Sao Thomé, the well-known centre of cacao production in the Gulf of Guinea, and as a substantial advance in cultivation has taken place during the last six years on the rapidly-increasing number of plantations, the industry has a promising future. The largest plantations are operated by Europeans and are situated on the slopes of the Kamerun Mountains, the total area given over to cacao production being about 26,000 acres, and the number of trees exceeding 6,500,000. The natives have also shown interest in cacao-growing, and many small farms are now found along the Sanaga, Munga, and Wuri rivers. In 1913 the exports of cacao were valued at £246,000, as against £202,000 in 1912 and £157,000 in 1911.

Bananas and other tropical fruits have been shipped to the European markets in increasing quantities, and the widening demand has given a considerable impetus to the exportation of this class of merchandise. Experiments have been made at Victoria in the cultivation of vanilla, ginger, pepper, cloves, and other tropical products. Gold and iron have been found in the colony, but no active exploitation of minerals has taken place.

Not only has there been a rapid industrial development in Kamerun, but the colony has also made considerable commercial progress. In 1904 the total value of its foreign trade was £828,000, whereas ten years later, in 1913, the value was £3,035,000, showing an increase of £2,207,000. The increase in the value of imports during this period was £1,201,000, and in that of exports £1,006,000.

About 80 per cent. of the trade has been with Germany, due largely to the good service offered by direct German steamship lines from Duala and Victoria to Bremen and Hamburg; but the United Kingdom has also done considerable business in Kamerun (about 15 per cent.), as in certain parts of the colony, especially inland, British firms have long been established and have carried on an active trade with the natives.

The principal ports on the sea-coast are Duala, Kribi, Victoria, Rio del Rey, and Kampo; the inland ports, near the frontiers of the neighbouring colonies, being Molundu (in the south) and Garna (in the north). About one-half of the total imports are entered through the custom-house at Duala, while Kribi is the principal port for exportation.

BAUXITE DEPOSITS IN BRITISH GUIANA.

Deposits of bauxite in British Guiana, according to official information, include the following, in addition to those already known:—

1. A substantial deposit in the north-west district of the Colony on the Yarikita River, south-west of its junction with the Amakura River, about twenty-eight miles from the coast at the mouth of the Waini River.

2. A deposit on the Arawari River, which is a branch of the Essequibo River, on the west side, near its mouth. This is fairly convenient for water transportation.

3. A deposit on the Ituna Creek, off the Berbice River, in the direction of the Kwitaro River, a branch of the Demerara River. The mineral from this deposit would have to be taken overland to the Demerara or Berbice rivers. Vessels of 16½ ft. draught can ascend the

Demerara River as far as Wismar, but above this point barges would have to be used.

According to a report by the United States Consul at Georgetown, all of the above-mentioned are on Crown lands, but no Government survey has been made of the deposits; consequently, their extent is not known, although it is believed that mining interests have explored the Arawari and Ituna deposits. The one on the Yarikita River is believed to cover a considerable area, probably extending into Venezuela; but unless the Amakura River is found to be navigable for barges, transportation to the coast would be difficult.

From the location of the known deposits, it would appear that bauxite exists in a strip of territory extending from the junction of the Yarikita and Amakura rivers across British and Dutch Guiana, and probably into French Guiana. The quality of the deposits around Wismar is believed to be equal to that found in the United States and France.

The Commissioner of Lands and Mines, in the course of a letter to an interested engineer, which was published in the local press, stated:—

"There are at present no existing regulations regarding the quarrying of bauxite, but it has been decided that the form of title, if issued, would be a lease to quarry bauxite. The area to be comprised in any one lease is 500 acres. No applications are likely to be approved until the terms on which land is to be leased for mining bauxite are settled by the Government. There is, however, no reason why applications for leases to quarry bauxite may not be made now, by handing in such applications at this Department with the filing fee of $5 (£1) on each application."

A lease which has been drawn up for bauxite lands, but which has not yet been accepted by the Government, provides that the lessees shall pay yearly in advance, without demand, on the first day of January in each year, to the Colonial Treasurer a certain annual rent of 20 cents (10*d.*) per acre or part of an acre, and shall, in addition, pay a royalty of 10 cents (5*d.*) per ton of 2,240 lb. for all bauxite obtained from the lands and exported from the Colony, and the minimum quantity of bauxite upon which, whether exported or not, royalty shall be payable each year shall be the total reached by taking 5 tons for each acre of the lands. The payment under this provision on account of the first year of the lease may be deferred until not later than the fifth year, and the payment on account of any other year of the lease must be made on or before January 10th in the following year. Minimum royalty payments may be averaged over five-year periods.

It is understood, adds the United States Consul, that several applications have been filed with the Department of Lands and Mines for the lease of Crown lands containing bauxite, but no action has yet been taken regarding them, and they are being held pending the decision of the Home Government.

ARTS AND CRAFTS.

Metalwork at St. Dunstan's Studio.—The annual exhibition of Messrs. Omar Ramsden and Alwyn Carr's work (held at their studio in Seymour Place, Fulham Road, S.W.) has been for years one of the shows most eagerly looked for by those who love beautiful metalwork. The exhibition naturally had a somewhat different aspect in war time, and there were more memorial tablets on view, and no large pieces of plate for City companies and the like; but, considering the conditions which are prevailing at present, and the impossibility of getting assistance except from mere boys, there was a great deal of work to be seen and a very fair proportion of it was new since last year. The object which attracted most attention—it was placed by itself quite away from the other exhibits—was the silver cup and cover designed and executed for Her Majesty the Queen. This is a beautifully proportioned work, much simpler in design than most of Messrs. Ramsden and Carr's important cups. The bowl and the shaft upon which it stands are perfectly plain, the foot is decorated with a narrow band of intertwined briar rose, and the same motive occurs again at the junction of the bowl and shaft. The cover is surrounded by a narrow cresting, and at its apex is a "noble rose," royally crowned, supported on a calix of thorn branches and smaller roses. The rose bowl designed for presentation to Sir John Furley on his eightieth birthday is much more in the artists' usual style. The smaller bowls, cups, caskets, table appointments and the like were what one has learned to expect from their makers—tasteful and distinctive, with no straining after originality at all costs. The memorial tablets were mostly small and simple; but they were well spaced, well designed and generally satisfactory in effect. Amongst the ecclesiastical work, the Crucifix and two candlesticks for a private chapel, executed in chiselled and wrought silver, stood out as the most conspicuous examples. The Christ figure was of the old clothed type, but conceived in a more modern spirit; and the candlesticks, which stood on either side of it, were massive and designed so as in some measure to repeat the vertical lines of the draped figure. The whole suggested a more satisfactory altar arrangement than some of those which have been recently shown elsewhere. The pastoral staff for the Bishop of Stafford was restrained and good in design. The churchwardens' staves for St. Margaret's, Lowestoft, and the verge for St. John's, Stamford Hill, were artistically treated versions of objects which in recent years have not had

much thought and care expended upon them, but which do offer possibilities to the designer who knows how to take them.

Toys.—From time to time through the winter there have been opportunities of seeing how the British toymaking industry was progressing. The Lord Roberts Memorial Workshops held a most successful show at Knightsbridge, and at all exhibitions of Arts and Crafts or Home Industries and the like toymakers have furnished their quota of exhibits. It was, however, the Christmas shopping season which revealed most completely the change which has come over the toy trade in the last two years; for it is from the ordinary shops that we are best able to judge of the type of toy which is really selling and finding its way to the children. Last year it was already apparent that the changed conditions were making a considerable difference in the character of the toys which were being sold. British-made toys were exhibited with labels attached to show that they were genuine home products, and a good many even of the most usual toys began to give evidence that their makers had some regard to their artistic appearance. This year, however, the change is even more marked, and it makes itself felt in all grades of toys, from the most expensive down to the penny toys sold in the streets—or, rather, down to what used to be the penny toys, for most of them nowadays cost a penny halfpenny or twopence. As a matter of fact, most of the toys sold this year for a penny were Japanese, and very pretty and dainty some of them were. Japan, indeed, has entered the market as the maker of the cheaper kinds of toys in a somewhat new guise, and is sending over not only what we used to see in the way of Japanese toys, but goods which directly take the place of toys which, before the war, used to be made in Europe. As to the English toys, there are still some spooky productions about, and some of the dolls are, to put it mildly, by no means beautiful—they remind one of a certain kind of pictorial art which does not profess to aim at beauty. Again, we suffer still from a certain number of "soft" toys, Teddy bears, rabbits and other animals which are softer than they were intended to be, and threaten to divide at awkward and unexpected points. Nevertheless, on the whole, there is an advance which is little short of wonderful, especially in the wooden toys of all sorts. It is no longer only Noah's arks that are works of art: it is no uncommon thing to find houses, villages, shops and other toys of the kind which are really things of beauty, and though some of them are expensive they are not extraordinarily dear, and they are sometimes quite moderate in price. Many of the jig-saw puzzles are from really good pictures, which do not suffer unduly from being cut up puzzle fashion, and horses and carts and a number of other toys are not only better made than they used to be in days gone by, but are planned and designed with some regard to beauty.

NOTES ON BOOKS.

ELEMENTARY QUALITATIVE ANALYSIS: A LABORATORY GUIDE. By B. Dales, University of Nebraska, and O. L. Barnebey, University of Wisconsin. New York: Wiley & Sons; London: Chapman & Hall. 1916. 5*s*. 6*d*. net.

In two important respects this book differs from the large number of first instruction books to which those who wish to learn something of qualitative testing can turn for instruction. First and foremost the wording is so exact and so unmistakable that the student can devote his whole attention to the subject-matter, instead of being driven to the verge of distraction by trying to solve verbal enigmas at a time when the attention should be exclusively incident upon the reactions, behaviour, and properties of the substance under examination. Short sentences, each complete in itself and without pronouns or expressions of uncertain meaning, are used in stating indications: thus on p. 132 we read as follows: "The residue is then ignited in platinum, and after cooling treated with HF. A platinum wire loop containing a drop of water is held in the vapors. A white cloud of silicic acid proves the presence of silicon." As a contrast, we may perhaps be allowed to quote from testing instructions given by a distinguished military officer, and published by the Royal Artillery Institution in 1896. "Now take your crystal of sapphire and try its point on your stone. If it does not scratch it and is scratched by it, the stone is a diamond beyond all doubt. If it does not scratch it, and is not scratched by it, it is a form of corundum." The second notable characteristic is a full realisation of what is likely to embarrass, mislead or endanger the student: that full realisation which only comes to the experienced teacher whose whole heart is in his work. The old concise statement that a precipitate is formed when by interchange it is possible to produce an insoluble substance, gives place to a short but lucid chapter on "The Principles of Qualitative Analysis," in which chapter there is a study of the action of mass, the intermediate colloid condition, dissociation, also such reversible actions and reactions as those in which hydrochloric acid, cadmium chloride, hydrogen sulphide, and cadmium sulphide are concerned. Among the various hints that suggest thoughtfulness on the part of the authors may be mentioned that on p. 86, as to the possible danger from acidifying a solution

containing a cyanide, the caution as to tentative experiments in relation to the possible presence of explosives (p. 122), the hint as to the silver crucible (p. 130), and the suggestion on p. 36 as to the use of library reference-books in cases of doubt or difficulty.

A Handbook for Cane-Sugar Manufacturers and their Chemists. By Guilford L. Spencer, D.Sc. Fifth Edition. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 15s. net.

The appearance of a fifth edition shows that this excellent little handbook continues to grow in popularity amongst cane-sugar manufacturers and chemists. Considerable advances in the theory and practice of the subject have been made during recent years, and in order to bring this edition up to date the book has been, to a great extent, re-written, and the chemical section has been revised to meet the conditions of the very large factories now in operation. As Chief Chemist in charge of manufacture at the Cuban-American Sugar Company, Dr. Spencer has had great experience of both the theoretical and practical sides of the work, and he writes authoritatively on the manufacture and analysis of sugar. The various processes in dealing with raw, plantation white and refined sugar are fully described, with numerous illustrations of machinery, etc., and the book concludes with a large number of reference tables which will prove extremely useful to cane-sugar manufacturers. In spite of the great amount of information which it contains, the volume is of such handy size that it can be easily carried in the pocket.

GENERAL NOTES.

Philippine Substitute for Gelatine.—A substitute for imported gelatine is made in the Philippines from a kind of seaweed brought in by the fishermen and sold in the markets. The native women use it for culinary purposes in the same way as gelatine is used in other countries, and foreigners also find it a good substitute. It is similar to the dried substance brought into the islands from Japan and China, which is extracted from various kinds of seaweed, dried and marketed in the form of bundles. It appears from a report by the correspondent at Manila of the United States Department of Commerce that the preparation of gulaman, as it is known, is not carried on in the Philippines on a commercial scale, but the dried article is imported from Japan and China, and is sold in the small shops. This commercial product is prepared by extracting the substance with boiling water, congealing the product, and then partially drying it before cutting into strips an eighth of an inch wide. The strips are then thoroughly dried for shipment. The yield is sometimes as much as 60 per cent. One part of the substance to 300 parts of water yields a jelly on cooling. The amount of raw seaweed brought in from the sea is not sufficient to meet the local demand for gelatine, but the cheapness of the imported article prevents a greater demand for the local product.

Radium Production in Bohemia.—According to a report by the United States Vice-Consul at Prague, 25,720 lb. of uraninite prepared for smelting, having an average value of about £97 per 100 lb., were produced in Bohemia in 1915, in the mining of uranium ore. Of the different uranium compounds there were produced in the Government mine in Joachimsthal 2,325 lb., of an average value of about £52 per 100 lb. The Government factory for radium compounds produced compounds containing 1·754 grammes (27·07 grains) of radium elements, having a total value of £43,036. The radium production in 1915 represented an increase of 0·879 gramme (13·57 grains) as compared with the production in 1914, the value of which shows an increase of £20,000 in round figures.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

January 24.—W. A. M. Goode, Hon. Secretary, National Committee for Relief in Belgium, "Relief Work in Belgium."

January 31.—Miss Ella C. Sykes, "The Work of the Y.M.C.A. in France."

February 7.—Robert Fortescue Fox, M.D., "The Future of British Spas."

February 14.—Lawrence Chubb, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

January 18.—Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel." The Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S., will preside.

February 13.—

March 15.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

April 19.—Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., Presi-

dent, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

MAY 17.—

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

JANUARY 18.—OCTAVIUS C. BEALE, Representative and Past President of the Australian Associated Chambers of Manufacture, "Imperial Industries after the War."

FEBRUARY 27.—ALFRED BIGLAND, M.P., "Imperial Assets and how to use them."

MARCH 27.—The HON. FREDERICK W. YOUNG, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

MAY 1.—CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

JAMES HARRIS VICKERY, LL.B., "German Business Methods."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

HOWARD LECTURES.

Monday afternoons, at 5 p.m.:—

WILLIAM RIPPER, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m.:—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 5, 12, 19.

JUVENILE LECTURES.

Wednesday afternoon, at 3 p.m.:—

ALAN A. CAMPBELL SWINTON, F.R.S., "Electricity and its Applications." Lecture II.

January 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 8...Brewing, Institute of (London Section), at the Imperial Hotel, Russell-square, W.C., 7.30 p.m. Mr. E. S. Salmon, "The Value of Hop-Breeding Experiments."

TUESDAY, JANUARY 9...Asiatic Society, 22, Albemarle-street, W., 4 p.m. Mr. H. Baynes, "The Messianic Hope and the Zoroastrian Prophecy."

Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor A. Keith, "The Human Machine which all must work." (Lecture VI.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. W. Brown, "Recent Progress in Dredging Machinery."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. W. S. Barrett, "Letters and Lettering."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. O. Bloch, "Plate Speeds."

Colonial Institute, Hotel Cecil, Strand, W.C., 8.30 p.m. Mr. W. Powell, "The Clarifying of British Commerce of Enemy Influence after the War."

WEDNESDAY, JANUARY 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Mr. A. A. Campbell Swinton, "Electricity and its Applications." (Lecture II.)

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Colonel R. E. Crompton, "Notes on Screw Gauges."

Geological Society, Burlington House, W., 5.30 p.m. 1. Dr. C. Lapworth, "Notes on the J. A. Douglas Collection of Graptolites from Peru." 2. Mr. H. A. Baker, "On the Palæozoic Platform beneath the London Basin and Adjoining Areas, and the Disposition of the Mesozoic Strata upon it." With an Appendix by A. M. Davies.

THURSDAY, JANUARY 11...Optical Society, at King's College, Strand, W.C., 5-9.30 p.m. Exhibition of Workshop Methods of Optical Testing.

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Messrs. F. Gill and W. W. Cook, "The Principles involved in Computing the Depreciation of Plant."

Geographical Society, Burlington-gardens, W., 5.30 p.m. Mr. J. C. Besley, "The Amazon River and Unexplored South America."

FRIDAY, JANUARY 12...Malacological Society, Burlington House, W., 8 p.m. 1. Rev. Dr. A. H. Cooke, "*Patella vulgata* L. and its so-called variety *Patella depressa* Penn." 2. Dr. A. E. Boycott, "The Occurrence of Manganese in Mollusca." 3. Mr. G. C. Crick, "Note on the holotype of *Crioceratites bowerbanki* J. de C. Sowerby."

London: Printed by WILLIAM CL[illegible] & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. B[illegible]S, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement

Journal of the Royal Society of Arts.

No. 3,347. VOL. LXV.

FRIDAY, JANUARY 12, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

THURSDAY, JANUARY 18th, at 4 p.m. (Indian Section.) COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel." The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., will preside.

[Fellows are requested to note that the hour of the meeting is 4 p.m.]

Further particulars of the Society's meetings will be found at the end of this number.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

JUVENILE LECTURE.

On Wednesday afternoon, January 10th, Mr. Alan A. Campbell Swinton, F.R.S., delivered the second and concluding lecture of his course on "Electricity and its Applications."

The lecturer began by showing some striking experiments with a Tesla coil, and its remarkable effects on a fluorescent screen. He also demonstrated how the current could be discharged from the operator to another person, or to other objects, and in this way he set fire to gunpowder and alcohol from his finger-tips. He then passed on to describe the carbon arc light, and projected on the screen an image showing the poles at a temperature of about 6,000° F., or half that of the sun.

The various kinds of searchlights and their mirrors were next dealt with and their mechanism explained. A new lamp for use in lantern projection (known as the "Point-o-Light") was shown, in which a globule of tungsten is raised to white heat in nitrogen, giving an intense light from a very small point. A mercury arc lamp was also exhibited, and attention was drawn to the way in which, owing to the small amount of red in the light from the lamp, red objects appeared black and human beings became corpse-like in colour.

It is not generally known that glass, and other insulating materials, at very high temperatures, become conductors of electricity; but the lecturer demonstrated this fact by passing a powerful electric current through two pieces of glass which had previously been raised to a white heat.

A pretty experiment was performed to show how a very small quantity of heat applied to a thermopile made of two metals (antimony and bismuth) connected together alternately, is sufficient to generate an electric current. The heat of the finger, when brought in contact with the instrument produced a marked disturbance of the galvanometer.

Mr. Campbell Swinton then proceeded to describe the selenium cell and its uses, the electric bell, the magneto bell, and the telegraph. When speaking of the Morse code, he showed an American instrument, known as the "practice buzzer," which automatically gives out messages in Morse, which the student attempts to write down as they are delivered.

In speaking of the telephone, the lecturer showed some remarkable photographs, taken by Mr. W. Duddell, F.R.S., of sound waves caused by speech, in which the vibrations varied from 40 to 40,000 per second. He then explained the action of the diaphragms in the transmitter and receiver of the telephone. The delicacy of a good instrument, he said, was such that an ordinary person could hear when the current was as small as one-billionth of a watt.

In conclusion, Mr. Campbell Swinton threw on the screen a number of photographs illustrating the action of the turbine, and also showing some of the great turbines themselves which are now used at Lots Road and elsewhere for generating enormous quantities of electricity.

On the motion of the Chairman, the Hon. Richard Clere Parsons, a cordial vote of thanks was accorded to Mr. Campbell Swinton for his very interesting course.

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

COAL AND ITS ECONOMIC UTILISATION.

By John S. S. Brame,
Professor of Chemistry, Royal Naval College, Greenwich.

Lecture II.—Delivered December 4th, 1916.

The need for research work in the composition of our various coals is patent when we consider how limited our knowledge of the subject really is, and how helpful it would be to the better utilisation of coals, especially the inferior varieties, if more definite knowledge were available of their constitution.

In the series of Cantor Lectures given by the late Professor Vivian B. Lewes in 1911 on the "Carbonisation of Coal," he dealt at some length on our knowledge up to that date of the nature of coal. With his usual clearness, he traced the various steps which had led to the conclusion that the different classes of coal were the result of the presence of varying proportions of decomposition products arising principally from cellulosic bodies (lignin, etc.), on the one hand, and the resinous constituents, gums, etc., on the other hand, of the original vegetation.

Burgess and Wheeler (*Chem. Soc. Trans.* 1911, 99. 653) had stated early in the year their opinion that "one type of compound in coal, and the most important type, is a degradation product of cellulose"—"the resins and gums originally contained in the sap of the coal plants form the cement of a conglomerate, of which the cellulose derivatives are the base."

Following an old nomenclature, Lewes termed the degradation products of cellulose "humus bodies," having the following approximate composition: Carbon, 63 per cent.; hydrogen, 5 per cent.; oxygen, 32 per cent., whilst the resinous residues had the approximate composition: carbon, 79 per cent.; hydrogen, 11 per cent.; oxygen, 10 per cent.

The resinous derivatives were regarded as the binding or cementing material, and the constituents which determined the formation of a coherent coke when coking coals are carbonised.

At a sufficiently high temperature they gave rise to distillation products which condensed in the shales of the coal measures, and, to some extent in the coal itself, as hydrocarbons.

He stated his opinion that these resinous bodies were of two kinds—one, easily oxidisable, saponified by alkalies and soluble in pyridine; the other not easily oxidisable (probably because oxidation had already proceeded nearly to completion) and forming an insoluble compound with pyridine.

If a coal had been subjected to high temperatures under pressure very little of the resinous matter preserved its original character sufficiently for identification.

Lewes regarded the different varieties of coal, then, as consisting principally of varying proportions of the humus constituents derived from cellulose, luted together by resins or resinous derivatives; and possibly also some hydrocarbons and carbonaceous residues, closely approaching to carbon itself. On distillation he believed that the humus bodies begin to distil about 300° C., giving off principally hydrogen, methane and the oxides of carbon; the resin bodies begin to distil at about the same temperature, the products consisting principally of saturated and unsaturated hydrocarbons and cyclic hydrocarbons (naphthenes). In his own mind, no doubt was left that the resin bodies and hydrocarbons were the cause of the "binding" when certain coals are coked, these bodies undergoing destructive distillation, leaving a pitch which acted as a cement.

Before proceeding to review briefly subsequent work, reference may be made to some old results of considerable interest which Smythe published on the results of extracting lignites with benzene and chloroform. The benzene extract (3 per cent.) was reprecipitated with petroleum ether and then the precipitate extracted with ethyl ether (*a*). The part insoluble in ether was extracted with acetone (*b*), leaving the insoluble part (*c*). Also by chloroform a body was extracted (1·8 per cent.) (*d*). The composition of these extracted substances is given below, and agrees with the composition of resins which have been found in masses in lignites:—

	From benzene.			Chloroform.
	a.	*b.*	*c.*	*d.*
Carbon .	77·2	79·23	77·75	76·45
Hydrogen .	8·26	12·83	11·77	9·91
Oxygen .	14·54	7·94	10·48	13·64
Melting-point	135°–140°C.	78–80°C.	80–83°C.	94°C.

Turning now to more recent work on the chemical side of the question, Bergius and Billwiller (*Jour. Soc. Chem. Ind.* 1913, 466) showed that by heating peat at a temperature of 340° C. in an apparatus constructed to withstand very high pressures—so high that water remained liquid—a black powder was obtained which, at

this same temperature and under very high pressure, underwent further change and resulted in the formation of an artificial coal. Unfortunately no analysis is given of the final product, but the results certainly indicate the general character of the changes through which cellulose probably passed in the formation of coal.

Several papers have also been published by Wheeler and his co-workers at the Government Laboratory of the Explosions in Mines Committee at Eskmeals. Burgess and Wheeler (*Chem. Soc. Trans.* 1911, 99. 649) had tentatively put forward the view that when coal is treated with pyridine, the insoluble portion was derived from cellulose, and that possibly the soluble portion represented the resinic constituents, although there was some reason against a definite conclusion on this point. Clark and Wheeler (*Chem. Soc. Trans.* 1913, 103. 1704) record the results of further experiments and show that part only of the pyridine extract is soluble in chloroform, and that the insoluble portion is of much the same character as the part originally left undissolved by the pyridine, so that this solvent is not without action on the "humus bodies."

They concluded that the treatment of coal, first with pyridine, and the subsequent treatment of the pyridine extract with chloroform, effect a complete—or nearly complete—separation between the resinous constituents and the degradation products of the celluloses.

In conjunction with C. B. Platt, a very pretty confirmation of these results was obtained by adopting a method discovered by W. J. Russell (*Proc. Roy. Soc.* 1908, B 80. 376) of testing the action on a photographic plate of resins and coals. When such substances are placed in contact with the film and maintained at 50° C. for some hours, on development an image results. Wheeler and Platt showed that whilst the portion of their coal which was insoluble in pyridine, and the portion soluble in pyridine but insoluble in chloroform, had no action on a plate, the portion of the latter which was soluble in chloroform (resin constituents) had a very strong action.

Pictet and Bouvier (*Compt. rend.* 1913, 157. 779) published results for the distillation of some 30 kilos of Montrambert (Loire) coal at a temperature of 450° C. and pressure of 15–17 mm. mercury. Four per cent. of tar, free from phenols, was obtained. After the considerable quantity of secondary bases which was present had been removed, on fractionating the remainder the first distillates resembled petroleum distillates; the later fractions had the odour of terpenes and menthol.

When this tar was distilled through an iron tube packed with coke heated to dull redness, a gas similar to ordinary illuminating gas, and a tar similar to ordinary tar were obtained. Pictet and Bouvier concluded that the greater part of the hydrogen and methane of the gas, and of the aromatic hydrocarbons and phenols of ordinary tar, are secondary products of the hydro-aromatic and other hydrocarbons formed at low temperatures.

Mr. Mclaurin, working on low-temperature carbonisation by a process in which the coal is heated by passing water gas directly from a producer through the coal, the temperature being about 400° C., appears to have obtained a very similar tar to that of Pictet and Bouvier; it was entirely soluble in sodium hydroxide; it contained practically no benzene or toluene, but about 6 per cent. of cresylic acids.

Jones and Wheeler were working at the time on similar lines to Pictet, and published their results a little later (*Chem. Soc. Trans.* 1914, 105. 140). Their results differed in one important respect, namely, that phenols (cresols and xylenols) were found in the tar. The temperature employed was 430° C., and it was pointed out that "at low temperatures coal in its entirety cannot be expected to reveal the nature of all the various classes of components which go to form the coal substance," because "only the resinic substances decompose to any great extent below 500° C.," so that "it is the resinous substances only, therefore, that must be regarded as having undergone examination by the method of attack described."

From the examination of the tar oil they concluded that it contained (1) unsaturated (ethylenic) hydrocarbons (40–45 per cent.); (2) naphthenes and liquid paraffins (40 per cent.); (3) phenols, chiefly cresols and xylenols (12-15 per cent.); (4) aromatic compounds, apparently homologues of naphthalene (7 per cent.), and other minor constituents.

Here we have the presence of phenols which Pictet and Bouvier did not obtain. This may have arisen from the totally different character of the coals used, or from the use of an upright retort by the French chemists, so that tarry products may have condensed and returned to the heated zone, whilst at Eskmeals the retort was inverted, the products escaping below.

A further contribution on the subject was published by Jones and Wheeler (*Chem. Soc. Trans.* 1914, 105. 2562) dealing with the products

obtained *in vacuo* at 350° C., which generally confirmed the results at higher temperatures, phenols being present again.

Summarised, then, as they were later (*loc. cit.* 1916, 109. 707), the Eskmeals results confirm the presence of the degradation products of cellulose, as the main constituent of bituminous coal, and of resinic derivatives. They claim that the former yield liquid distillates in small amounts and consisting largely of phenols. The resinic constituents, on the other hand, lose half their weight at 450° C., the liquid distillates consisting of "all the components of tar obtained by the low-temperature carbonisation of coal, with the exception of the phenols which are absent."

Although, then, the phenols are claimed to be formed only from the cellulosic bodies, and that only the resinic bodies are claimed to have undergone examination by this method of low-temperature distillation, yet *phenols are present to the extent of* 12 to 15 *per cent.*, and to the extent of 17 per cent. in the tar from a Durham coal (*loc. cit.* 1914, 2564). If the phenols are not formed from the resinic components and the cellulosic degradation products do not undergo appreciable decomposition, as claimed, from what source have they been derived?

It is well known that low-temperature tars are characterised by a high content of phenols (cresols and xylenols). Attention might again be directed to the absence of phenols in Pictet and Bouvier's work, and this is more in accordance with the claims of Wheeler and his colleagues than the results they obtained themselves.

Criticism may be directed against the use of pyridine, although, so far, it has proved the most useful solvent in the extraction of coal. Lewes pointed out the overwhelming evidence that pyridine had entered into combination with both the insoluble and soluble portions in nearly every record of work which had been published. Harger (*Jour. Soc. Chem. Ind.* 1914, 33. 389) records experiments he had made, and directs attention to the Eskmeals results. From Clark and Wheeler's data on Silkstone coal he shows that it is evident that all the fractions contained more nitrogen, in total, than the original coal, and calculates that pyridine amounting to 4 per cent. on the coal was retained; further, that considerable oxidation had occurred in both the pyridine and chloroform extracts, the oxygen in the latter being increased to 60 per cent. A further important point noted by Harger was that the chloroform soluble portion did not appear to be present in the original coal, as such. He concludes that with pyridine there is "some kind of simplification which yields the pyridine soluble matter, a process similar to depolymerisation and due to the action of pyridine and heat."

In the main these actions probably have not affected the general conclusions of Wheeler and his associates, but one would have expected Harger's criticisms to have been referred to in subsequent papers by Jones and Wheeler.

These authors have put forward various speculations as to the chemical structure of the types of compounds likely to be present in coal which gives rise to the various products on low-temperature distillation; but until the difficulty of accounting for phenol, above referred to, and until the "resinic" bodies have been obtained free from combined pyridine, or by the use of other solvents obtained in a more pure condition, such speculations would appear premature.

In general, however, the following conclusions would appear fully justified. In the first place, it is concluded that the free carbon, usually assumed to be present in coal, is improbable—on the grounds that any bacteriological changes would be unlikely to produce it, and that the temperature to which the coal during, or subsequent to, formation has not been subjected to temperatures high enough to result in such complete carbonisation. Further, the pressure would be against such complete carbonisation. (In many coals there is often a considerable amount of "mineral charcoal," the dant or "mother of coal," which in all probability does contain free carbon.)

The cellulosic derivatives are regarded by Jones and Wheeler as probably few in type, whilst the resinic derivatives are very complex. Several hydrocarbons have been obtained from coal by them and other workers.

An extensive investigation of coal, using phenol as a solvent, was carried out by Frazer and Hoffman in the United States Bureau of Mines laboratories (Tech. paper 5, 1912). On the basis of the pure coal substance phenol dissolved 10·9 per cent. The phenol extract was further treated with a great variety of solvents and the products analysed. The authors concluded that some nearly pure compounds had been isolated, but the amounts obtained were so small that this could not be definitely established. Some, however, appeared to be almost pure hydrocarbons, containing small quantities of oxygenated compounds. Amongst the highly-

oxygenated compounds was one agreeing closely with the formula $x(C_5H_7O_2)$:—

	C.	H.	O.
Product	60·0	7·06	32·94
Formula $C_5H_7O_2$ . .	60·6	7·07	32·40

Parr and Hadley, by extracting with phenol at 110° C. for twenty hours, found that all the coking constituents and the greater part of the volatile matter were removed from the coal; they make also one very significant observation—that the elementary composition of the coal, the extract, and the insoluble residue were practically the same, and this applied also to the gaseous products of decomposition of each.

More recently F. Fischer has employed liquid sulphur dioxide and has extracted typical resins from lignites. This solvent may well prove of considerable service in the chemical examination of coal, being probably preferable to most of the organic solvents employed. It has proved of considerable value in the examination of petroleum, and has already been employed on a commercial scale for refining of petroleum distillates.

From the above *résumé* the need for extended research is evident, and this will no doubt be vigorously prosecuted under the grant recently announced for the investigation of our coals. Probably the application of methods which have thrown so much light on the composition of alloys, the examination of microstructures developed by solvents, together with the chemical examination of the extracted bodies from larger masses of the coal, will prove a fruitful line of attack.

Turning to the application of coal in practice, so numerous are the purposes for which it is employed and so varied the methods of employment, that only a brief reference will be made to the more important uses, particularly with a view to pointing out how the more economical use may be attained.

Taking first into consideration the use of raw coal in metallurgical and other furnaces, the long hot flame from bituminous coal is usually required, but the conditions of combustion are such that, in general, very inefficient use is made of the coal. In the first place, the efficiency of heating furnaces is usually very low: with reverberatory furnaces under the best conditions it is probably about 15–17 per cent.; over 75 per cent. of the heat units are lost in the flue gases. The flaming tops to the chimneys of large numbers of heating furnaces are evidence of the big heat losses. The application of the regenerative system, so successful with gaseous fuels, is very difficult with solid fuels. Moreover, such furnaces are very bad smoke producers. Whenever a mass of material is being heated up by luminous flames, the great difference in temperature leads to chilling and the formation of smoke.

In the use of raw coal for steam-raising, it must be recognised that some coals give such excellent results in practice that they have acquired a relatively high market value. For hand-firing a good-sized coal is requisite, and a great deal depends on the skill of the fireman. Suitable coals have consequently been worked out for this purpose, to the neglect of somewhat inferior coals, or the same coal in a broken condition.

The introduction of mechanical stokers has been a considerable factor in economy, in two directions: first, in permitting of the use of small "slack" coal, which was unsuitable for hand-firing; secondly, in facilitating more regular and complete combustion, with large reduction in smoke, because of the principle of regular feeding of the furnace, so avoiding rushes of unconsumed gases, and further by allowing better adjustment of the air supply, which contributes greatly to the efficiency of the boiler.

However good the boiler practice may be, there are inevitable losses which reduce the efficiency to possibly some 70 per cent. Heat is lost in the flue gases, this being the principal loss. The flue gases must escape hot with "natural" draught to give the necessary air supply. Reduction of these losses is effected by the use of economisers, where heat is made use of in warming up the feed-water. Then other inevitable losses occur with the hot ashes, and, to a certain extent, with incomplete combustion. On the other hand, very low efficiencies are common through avoidable causes. Large excess of air through the furnace carrying away an excessive proportion of the heat is one of the most common. Again, there may be incomplete combustion, in most cases evidenced by smoke, although it may exist without visible evidence, carbon monoxide being formed instead of carbon dioxide, when approximately two-thirds of the heat it is possible to produce per unit weight of carbon is lost for every unit so consumed.

The scientific control of the combustion process is a great factor in fuel economy. By the analysis of the flue gases the engineer in charge can ascertain if any unnecessary excess of air is passing through the furnace, or i

combustion is incomplete. The percentage of carbon dioxide in the flue gases is usually a sufficiently good guide as to excess air, and fortunately this is a very easy gas to estimate. Automatic carbon dioxide recorders are now frequently installed, and result in very considerable economy in fuel.

Pulverised coal offers considerable promise as an efficient boiler fuel; probably in this form it can be used more efficiently than in any other form. Rotary cement kilns are commonly fired with coal dust carried into the furnace by an air blast; a long fierce flame rivalling that with oil fuel is obtained, and this is quite free from smoking propensities. Trouble is sometimes experienced through the dust from the ash; sometimes it even fuses on the surface of hot pipes and plates. It would appear that the cost of drying and pulverising the coal is about 1*s.* 6*d.* per ton. It is doubtful whether the system offers any advantages over a good mechanical stoking plant, when the whole of the factors are taken into account.

Another method of utilising small coal as fuel is that of briquetting, large quantities of the small steam coal being disposed of in this way in South Wales. It is notably on the Continent that briquetted coal has been most extensively adopted, and at one time this industry formed a profitable outlet for the surplus pitch from English gasworks. In this country the industry is confined chiefly to the South Wales coalfield, which produced, in 1914, 1,599,713 tons of briquettes out of a total British production of 1,840,465 tons. Ninety-six per cent. of the coal briquetted was small Welsh steam coal.

In briquetting the coarsely-ground coal is dried, mixed with from 6·5 to 8 per cent. of its weight of pitch, passed through a disintegrator, thence to a heater to soften the binder and on to the briquetting machine. One advantage of briquettes is their regularity of shape, which gives to briquetted fuel a high stowage value—an important consideration in shipment.

The use of "prepared" fuels from coal is very extensive. These may be classified as: Solid fuel, coke; liquid fuels, benzol and tar oils; gaseous fuels, coal and coke-oven gas, producer gases.

No more than a reference is necessary here to the general use of hard metallurgical coke for blast furnaces and other metallurgical purposes, but more specific consideration may well be given to ordinary gasworks coke, which is a by-product, for industrial use. The subject is of considerable economic importance, because its production is accompanied by the recovery of the other valuable tar products and by the gas; further, it provides an outlet for the surplus coke from gasworks, of which several million tons are produced annually.

The yield of coke in ordinary gasworks practice is about 65 per cent. of the coal carbonised. On the total carbonised annually this will amount to some 11 million tons, and although about 15 per cent. will be required to carry out the carbonisation, and probably 1½ million tons is converted into water gas for admixture with the coal gas, there is a large surplus to find economical outlets for.

Considerable attention has been given to its use for steam-raising. Owing to the almost entire absence of volatile constituents coke is difficult to ignite and requires a strong draught, so that forced or induced draught has to be installed. The London Coke Sales Committee has developed a special grate for the use of coke. The conditions of combustion are different from those with coal, because there is very little gas to burn, except perhaps a flame of carbon monoxide, the whole of the fuel being practically consumed on the grate. Less excess air is consequently required for combustion, thus reducing heat losses in the flue gases. An advantage is the absolutely smokeless combustion. Because of its porous nature the stores and bunkers hold a smaller number of potential heat units than with coal, and the ash is, of course, higher than with coal, averaging about 1·4 times the coal ash. This may lead to clinkering, since the fuel is all burnt on the grate under good draught, so that high calorific intensity is obtained.

It has been claimed that the sulphur in coke is detrimental, but it is difficult to see why this should be, for during the production much of the original sulphur escapes in the gas and tar, coke containing usually about 70 per cent. of the sulphur originally present in the coal.

Very successful results have been obtained with coke for steam-raising. At Deptford, over a period of one month, 16 per cent. was saved in fuel costs. Steam-driven lorries are working on coke, as are also colliers belonging to some London gas companies and steam tugs. With the present high prices of coal and difficulties of delivery, many power-station engineers are either already employing coke or putting in hand the necessary alterations for its adoption.

With water-tube boilers, the probable development will be on the lines of an internal producer,

primary air being used to gasify the coke in an arched chamber, through openings in which the gases will pass, then mixing with the secondary air to complete combustion. In this way smokeless flames would result and the brick arch would form an efficient radiating surface. The drawback would be that extensive alterations would be requisite if coal had to be burnt.

Another development in the use of coke of quite recent date is the briquetting of the small waste which accumulates at gasworks, and is of little value. This method is of considerable importance at present because, with the large production of tar and the closing of the Continent to the shipments of pitch, this material is accumulating at most works, and the use of a portion to assist in converting the unmarketable coke into a fuel of the selling value of 12*s*. 6*d*. per ton is a double economy.

A plant installed at Smethwick Gas Works over a year ago has proved very satisfactory. Through the kindness of Mr. Vincent Hughes I am able to exhibit samples of these briquettes.

In manufacture the coke dust is graded to pass a ¼-in. mesh sieve, and is mixed with 8 per cent. of pitch, this mixture being fed to the disintegrator. In the heater a little tar is added, and the hot mass briquetted at 6 tons pressure. A full description of the plant will be found in the issue of the *Gas World*, November 11th, 1916. At Smethwick the plant relieves the works of about one-sixth of the pitch made. If the coke breeze were also briquetted, one-third of the pitch could be utilised.

The briquettes are suitable for closed stoves, ranges, etc., and form the only boiler fuel used at the works. For the usual open grate the draught is insufficient to burn them without a proportion of ordinary coal.

Similar plants for briquetting, but of greater capacity, are being installed at Coventry and Northampton.

The other "prepared" fuels from coal are the tar and tar products, and the gaseous fuels, coal or coke-oven gas and producer gas. It will be convenient to leave the consideration of the gaseous fuels for the present, and deal with the composition and important products derived from tar.

The use of tar (or tar products) as fuel will depend entirely upon the quantity produced, and the market for the valuable raw materials it yields. At present all tar yields more valuable returns after distillation, and the demand for many of its products for munitions is so great that it is a national necessity to utilise all available tar in this way. On the other hand, within quite recent years the price of tar was so low that an outlet for fuel purposes, for road work, etc., was found.

The economic use of coal is closely associated with the question of the by-products—ammonium compounds and the tar—many important chemical industries being dependent on the latter, whilst the small quantity of nitrogen in coal—averaging about 1·4 per cent.—furnishes our principal supplies of ammonia compounds. The sulphate of ammonia alone is a most important material as a fertiliser, and its importance to agriculture can hardly

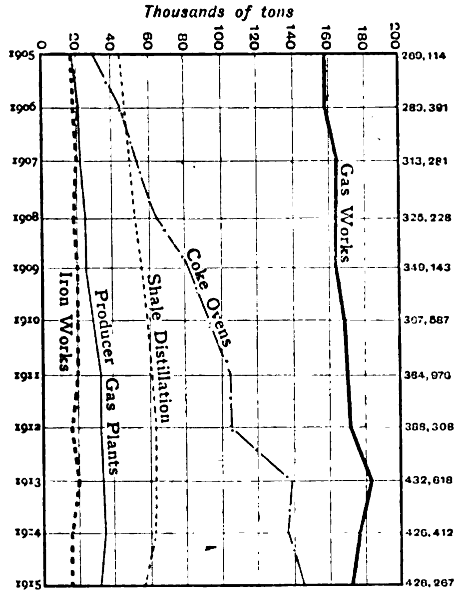

FIG. 3.—PRODUCTION OF AMMONIUM SULPHATE.

be overestimated. In the increased production of home-grown foodstuffs, generally admitted to be a pressing question, it must undoubtedly prove an important factor. It is one of the romances of science that by means of sulphate of ammonia we are actually returning to plant life nitrogen derived from a previous vegetation which flourished millions of years ago.

The total output of this salt in 1913 was 432,618 tons. Under the best conditions of carbonisation not more than the equivalent of 20 per cent. of the nitrogen is obtained as sulphate; about 70 per cent. remains in the coke, and can be mostly recovered when the coke is gasified in a producer. When bituminous coal is gasified in producers a high yield of ammonium sulphate is 90 lb. per ton, which equals a conversion of about 68 per cent. of the nitrogen into sulphate.

The great increase in the production of ammonium sulphate in recent years will be seen from Fig. 3 (p. 155), which shows the total annual production, and the yield from gasworks, coke ovens, blast furnaces and ironworks. The effect of the introduction of recovery plant in coke-oven practice is very marked.

Besides the sulphate, the ammoniacal liquor of the gasworks may be worked for strong ammonia which is liquefied for use in refrigerating machines, for strong ammonia solution, or for other salts, such as the chloride or nitrate, the latter forming the main ingredient of an important class of explosives, used for both mining and military purposes.

Other valuable nitrogen compounds now extracted from the distillation products of coal are cyanides, which find application in the extraction of gold.

The yield of first products from 100 tons of coal is shown below:—

Benzene, the most important of the hydrocarbons obtained from the tar, has proved a valuable fuel for motor engines. In addition to that derived from the tar, further quantities may be obtained by washing the gas with heavy oils which dissolve the benzene and yield it up again on distillation. Ordinary coal gas scrubbed in this way has its illuminating and calorific value reduced very materially, and it is not possible to carry this oil scrubbing to the point of complete removal of the benzene without detracting too much from the value of the gas. Coke-oven gas can, however, be stripped of benzene.

The importance of benzene as a fuel in lieu of petrol is very great; ample supplies of such a home product would do much to check artificial prices for petrol. It has been estimated that it would be possible to produce annually some twelve million gallons from gasworks and sixty million gallons from coke ovens, if all coal were treated in recovery plant.

100 TONS BITUMINOUS COAL.

Coke.	Sulphate of Ammonia.	Cyanide of Sodium.	Gas Tar.	Coal Gas.
65 tons.	$1\frac{1}{4}$ tons.	2 cwt.	975 gallons (5 tons).	1,100,000-1,200,000 c. ft.
Metallurgy. Heating.	Agriculture. Explosives. Soda manufacturing. Refrigeration.	Extraction of gold, etc.	Motor fuel. Explosives. Dyes. Drugs.	Light. Power. Heating.

The tar is the most important of the by-products obtained, and certainly no substance has yielded so many valuable products for the service of man. It must be clearly realised that the tar contains but few bodies which are utilised directly after separation, the principal being benzol, solvent naphtha, carbolic acid and its cousins, the cresylic acids. All the vast number of beautiful dyes, of valuable drugs, disinfectants, flavouring essences and perfumes, and photographic developers are the outcome of the work of the chemist on the raw materials furnished by the tar.

In the first place the tar is distilled and portions collected at various temperatures, so yielding a number of fractions, which by further treatment yield ultimately pure products. The general scheme of fractionation and the principal products from each fraction are shown below:—

Benzene is also employed for cleaning purposes (cloth, fabrics, etc.), and quantities are now converted to synthetic phenol (carbolic acid), from which picric acid (Lyddite) is prepared.

Another hydrocarbon closely allied to benzene is toluene, for which there is a great present demand for conversion into trinitrotoluene (T.N.T.), the powerful high explosive. Quantities are now obtained by oil scrubbing of the gas and also synthetically from benzene.

Phenol (carbolic acid) can be extracted directly from the light oil and carbolic oils by washing with caustic soda; also the closely-allied cresylic acids. All yield high explosives on nitration.

The importance of tar products for furnishing munitions of war is very great. The necessity

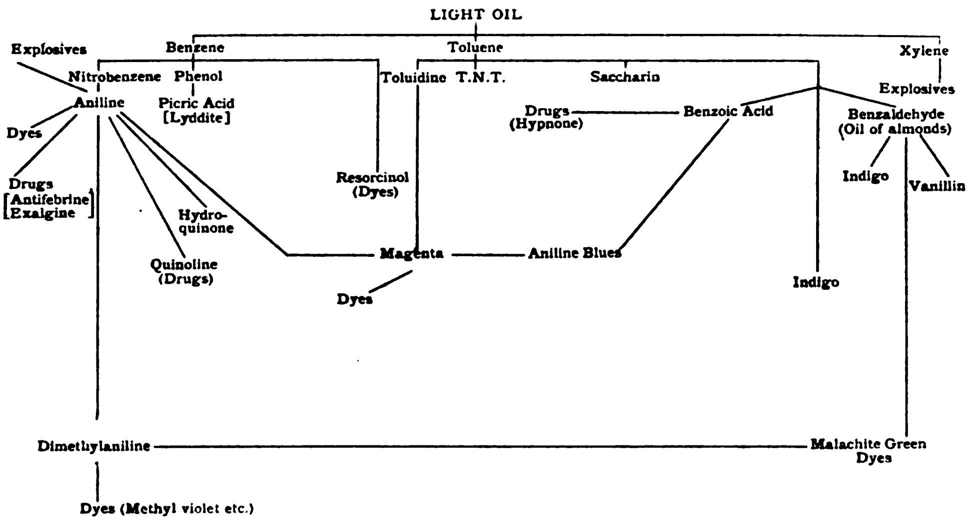
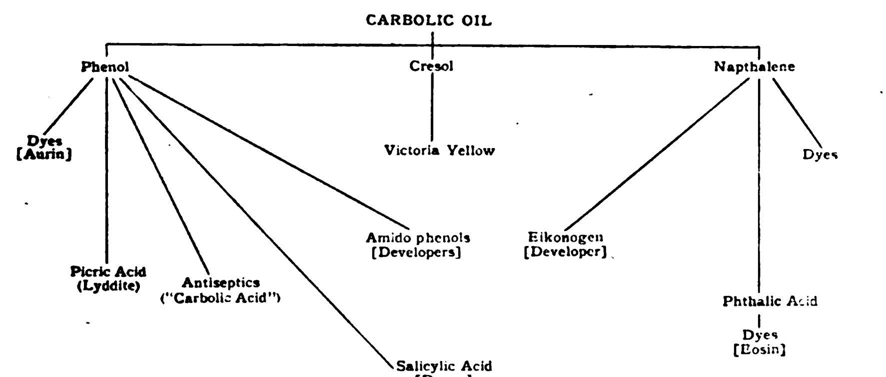
for increasing our output of the principal raw materials was soon evident, and the manner in which the managers of gasworks and coke-oven plants have responded to the demands has been wonderful.

It is impossible here even to outline the chemistry of the processes by which the raw materials furnished by the tar distiller are converted into dyes, drugs and other valuable derivatives. The general relationship of some of the principal of these to the original material is shown in the following diagrams:—





ENGINEERING NOTES.

Cable Telegraphy.—A new invention, devised by Mr. J. B. Dixon, has been in practical operation on certain of the Atlantic cables, and is reported to have given remarkable results, the speed of operation in the commercial handling of cable messages having been increased upwards of 125 per cent., while in tests far greater speeds have been attained. The gain in speed is due to the use of selenium cells to amplify the signals received, and to the use of means for obtaining, from one or more sources of illumination, a very large number of light beams, concentrated coincidently upon selenium cells, and deflected by a line galvanometer across the surface of the cells, the effect being that a very intense illumination of the cells is obtained. It is found that the practicable speed of operation increases as the intensity of illumination increases. The selenium cells operate a siphon recorder or a relay. There being no physical connection between the recorder or relay and the line galvanometer, the inertia and frictional losses present in the older magnifying and recording apparatus are largely eliminated, the more so as in the new system the amplitude of vibration of the galvanometer coil

is, in general, much less than in the case of the older apparatus. It is stated that Mr. Dixon employed forty-five separate light beams, all derived from one 400 candle-power tungsten lamp, and all concentrated on a thin galvanometer mirror 5 in. long and ⅜ in. wide. These light beams were reflected from the galvanometer mirror, in one case, a distance of 7 ft. 6 in., and were then re-reflected a further distance of 7 ft. 6 in. to the selenium cells, the light beams being concentrated coincidently upon the cells. With this apparatus, working over one of the trans-Atlantic cables, the normal rate of operation of which is less than two hundred letters per minute, a speed of 450 letters per minute and higher was obtained in the regular commercial handling of business, and still higher speeds have been obtained on tests, with signals fully readable as to size and character.

Coal in Spitzbergen.—The Norwegians are showing much enterprise at present in the matter of establishing coal-mining in Spitzbergen, and the prospects appear to be encouraging. The nearest markets for the Spitzbergen coal are Northern Norway, Kola, Archangel, Iceland (where, however, coal is also being mined), and the Faroe Islands. The *Times*, in its Engineering Supplement, states that the Norwegian Spitzbergen Syndicate will have shipped some 20,000 tons of coal to Norway before navigation closes for this year, and extensive preparations are being made for the future, especially as regards the welfare of the men. For about 1*s*. 9*d*. a day the men get good board and lodging, light and heat, and they all seem anxious to stay over the winter. The Norwegian Coal Fields, Spitzbergen, another recently formed undertaking, has acquired the deposits of the Spitzbergen Coal and Trading Company. The area is of considerable extent, and has been carefully examined. The deposits are calculated to contain 500,000,000 tons of coal, the quality of which has been thoroughly tested in practical use in Norway. The production is expected to reach 70,000 tons during the second year of working, and when the plant has been extended an annual production of 150,000 tons is expected. An expedition, sent from Norway during the summer, to examine the area held at Green Harbour and Advent Bay by the Svalbord Coal Mining Company, discovered some deposits not previously known. A portion of the same seam had indeed been found in the Hiorth coalfields on the east side of Advent Bay, but was supposed to form part of a seam already known. It now, however, appears to be an independent deposit, having a great horizontal extension in the area of the Svalbord Company south-east of Advent Bay. That company's coalfields at Advent Bay are calculated to contain 680,000,000 tons of coal, taking into account the ten seams likely to prove worth working. At Green Harbour, the coalfields are estimated to contain 200,000,000 tons. Working plans are to be completed this winter on the basis of an annual output of 200,000 tons, and the erection of plant will be proceeded with next summer.

Novel Method of Erection adopted in Roadway Bridge Span in America.—Exceptionally daring and successful for work of such magnitude was the method of erecting the trusses for the 592 ft. three-hinged arch roadway bridge crossing the Colorado River at Topock, Arizona. This span ranks third among arch bridges in that country, and is the longest roadway bridge of its kind. The bridge is located near the Red Rock cantilever bridge of the Santa Fé Railway, crossing the Colorado River on the route of the national "Old Trails" highway. The river at this point is very swift. During construction of this bridge last winter it often ran from fifteen to eighteen miles per hour. The river bed is a fine silt, very changeable, the depth of this silt being from 80 to 100 ft. at the bridge site. The main stream is under the California half of the arch span. A rise of 1 ft. would often result in scouring out 25 ft. of the silt, and after the completion of the bridge a rise of 4 ft. took out all the falsework except the piling under the centre tower. The total length of the steel superstructure is 832 ft., including the main 592 ft. arch of thirty-two panels at 18 ft. 6 in. each, with a rise of 100 ft., and approaches at each end consisting of two 56 ft. plate girder spans carried on steel bents and towers. The main arch trusses are 25 ft. centre to centre, while the approach girders are 22 ft. on centres. The floor system consists of rolled beams, supporting a timber floor for a 17-ft. clear roadway, suspended from the middle arch and supported by each abutment end. The extremely treacherous conditions of the river bed at the site, as described, made the usual method of erection by the use of high falsework not only very expensive, but also dangerous. As will be seen by the description given below, it was possible to erect the trusses in a nearly horizontal position with the use of very little temporary falsework. The trusses on the Arizona side were supported by several posts resting upon the sand. The California trusses on the other side of the river were supported upon pile bents, with the piles driven about 25 ft. into the silt of the river bottom. These pile bents on the California side made a working floor for the erection derrick, and on this floor pony bents carried the steelwork. The piling was driven by a stiff-leg derrick, on which the extreme length of boom used was 120 ft. The scheme of erection thus adopted, which worked out with great economy and with complete satisfaction, included the construction of a temporary steel tower upon piling at the centre

of the span, using floor steel for the columns and bracing and hoisting apparatus with which the half spans could be revolved vertically into place around the end pins by raising them at the centre. It was planned to avoid danger from a sudden washout of the falsework, under the California trusses, by supporting the trusses on the centre tower and on the lower pin. The main abutments were first constructed, the end hinges set in place, and the trusses on the Arizona side built out on the sand bar from that side and continued to the centre hinge. Piling was then driven into the river from the centre tower to within approximately 60 ft. of the California end hinges. The California end hinges were next set, and erection of trusses then proceeded toward the centre tower, cantilevering across the 60-ft. gap by shore supports. Thus, should the falsework fail, the erected portion of the California trusses could be held by the central tower and the lower end hinges. All joints in the main trusses were riveted up. Lateral struts and lateral diagonal rods were bolted loosely in position so as to allow some slight movement between the trusses during erection. Sufficient lateral bracing near the centre hinge was left out to allow both half spans, when lying in the horizontal position, to pass the erection tower, which was made just wide enough for sufficient clearance. In the abridged article by the *Engineering Record* of New York, the details of the temporary tower are fully described. Two 30 h.p. engines located on the Arizona shore were used to raise the half spans after they had been riveted up complete except for the lateral bracing, with end pins in position. Using a ⅞-in. cable and a 9-sheave upper block with an 8-sheave lower block, the California half span was raised first, the actual working time being about 15 minutes, and the total time 40 minutes. These trusses were raised about 3 ft. higher than their final position in order to allow the Arizona trusses to pass. This gave about 6 in. clearance. The sheaves were transferred to the other corners of the tower, and the Arizona trusses raised in a total time of about 30 minutes, and the same actual working time as the California trusses. About six hours were then required to lower the two sides together until the crown hinge came to a bearing. The auxiliary half hinges were then riveted up. So accurate was the shopwork that the final position of this crown joint when connected up was within ½ in. vertically and ⅜ in. laterally of the true position, allowance being made for temperature variations. The centre hinge of the ball-and-socket type is of cast steel, with a spherical compression bearing. The milled head of convex bearing surface fits the concave spherical surface of a nickel-steel compression piece carried by the cast-steel hood attached to the other truss. For adjustment, steel shims of varying thickness could be inserted in the pan of the hood back of the nickel-steel compression piece. For the purpose of tying the trusses together at the hinge and resisting any possible tensile stress which might be developed at the leeward hinge under excessive wind pressure, auxiliary leaf hinges were provided using 6-in. plates and bent angles to form a hinge flexible under rise and fall of the arch. The total weight of the two arches is 360 tons, and the bridge was completed and accepted on February 20th, 1916.

CORRESPONDENCE.

"ECLIPSE OR EMPIRE."

In your note on the book "Eclipse or Empire" in the *Journal* of November 3rd, 1916, you charge Dr. Gray and myself with reproducing a "sadly fallacious set of tables" from which you say the reader is asked to believe that the American operative is the equal of from one and a half to three English wage-earners. The argument on which this conclusion is based is in no way dependent, as a matter of fact, upon these figures. It rests on such indisputable facts as that wages in America are two or three times as high as they are here, though the wholesale selling prices of many commodities are no higher; and that, as shown by an American Government report issued in 1904, the American bootmaker produced 700 to 800 pairs of boots against the Englishman's 300 to 400 on the same machine. The figures quoted from the two Censuses of Production are cited merely as an illustration of a tendency established by a great mass of cumulative evidence. I do not doubt that these figures are "fallacious" in detail. It is almost inevitable in figures covering the activities of entire nations. But may I express my surprise at the particular instance you have selected for criticism? The only importance these figures have, so far as the book is concerned, is the presumptive evidence, such as it is, which they afford that this country is failing to keep pace in the industrial race. You reply that the American and English silk industries have nothing in common but the name, and therefore the figures are valueless. Unhappily the British silk industry is one of those in which no proof from this or any other source is required of the relative failure of our trade. "The silk industry," as Mr. Farrell, one of the largest British silk manufacturers, remarks in his article in "Eclipse or Empire," "is one which—for various reasons, mainly economic—has declined very considerably in this country since the middle of the last century." The decline of British industry—and the danger involved in it—is the warning which the book was written to give. In the case of silk, the fact is so thoroughly established that the precise interpretation of the figures is really irrelevant.

SAMUEL TURNER.

The note in question had reference simply to one or two specific points of textile interest contained in Messrs. Gray and Turner's book, and made no profession of evaluating its total contents. No probable harm can come of disseminating a crude comparison among persons qualified to realise the difference of the industrial situation in the two countries. Upon the other hand, mischief may be done by sowing broadcast figures which are very far from mirroring the whole truth. The authors confessedly found their tables in the English monthly reviews. They may be referred for more of the same style of thing to the original source, a pamphlet on "Foreign Tariffs and Industrial Conditions," issued from the Government offices at Washington in 1913. They will find that only a selection from the originals was made by the compiler.

The comparisons of textile efficiency are hopelessly vitiated by the differences of character in the goods produced, and it will be found that British industries, which in seeming have not a statistical leg left to stand upon, have remarkably little trouble in vindicating their real character in the open markets. The remarks were not intended to disparage Mr. Turner's well-meant efforts to spur British industry on to new enterprises. There may be a difference of opinion, however, as to the help given in that direction by figures so far divorced from fact. The silk industry was instanced as an extreme example of the fatuity of the comparisons; but Mr. Turner is at liberty, if he chooses, to turn to the cotton and woollen and worsted trades, which have by no means declined in the last half century.

THE WRITER OF THE NOTE.

OBITUARY.

SIR HOWARD WARBURTON ELPHINSTONE, BT. —By the death of Sir Howard Warburton Elphinstone, which took place on the 3rd inst. at his residence in Wimbledon Park, the Royal Society of Arts has lost its third oldest member, he having been elected in 1859.

Sir Howard was born in London in 1830. His grandfather was created a baronet for services rendered in the Peninsular War, and his father, who represented Hastings and subsequently Lewes in Parliament, was for some years a member of the Bar. Sir Howard was educated at Eton and at Trinity College, Cambridge, where he obtained a scholarship. He was Seventeenth Wrangler in the Mathematical Tripos of 1854. After acting for some time as Librarian of his College, he was called to the Bar by Lincoln's Inn in 1862; in 1869 he was appointed Lecturer to the Incorporated Law Society; and in 1889 Professor of Real Property to the Inns of Court. In 1895 he became Conveyancing Counsel to the Court.

Sir Howard's name has been well known for many years as the joint author with Mr. Key of "Precedents in Conveyancing." Besides this his principal works were: "Introduction to Conveyancing," 1871; "Patterns for Turning," 1872; "On the Interpretation of Deeds," 1886; and "On Searches," 1887; and he was also joint editor of "Goodeve's Real Property," 1897, and "Goodeve's Personal Property," 1892. He succeeded to the baronetcy on the death of his father in 1893.

SECOND LIEUTENANT CHARLTON WILLOUGHBY HOUGHAM FOORD.—Second Lieutenant Charlton Willoughby-Hougham Foord, Machine Gun Corps, died on December 19th, 1916, of wounds received on the previous day. He was the only son of Alfred Stanley Foord, of Laurel Road, Wimbledon, and was just thirty-one years of age. He was educated at Dulwich College, and after having served an apprenticeship with Messrs. Gwynne, engineers, Hammersmith, he entered the firm of Messrs. Marks and Clerk, consulting engineers and patent agents, being in charge of their branch office in Southampton Buildings from March, 1911. He was passionately fond of music, and particularly interested in wind instruments, himself playing the clarionet, and in February, 1914, he contributed an article "Air Pressures in playing Reed Instruments" to the *Philosophical Magazine*, the result of experiments made by himself. Keenly interested in shooting, he was an excellent shot, and entered for some notable competitions at Bisley. He enlisted in June, 1915, in the R.N. Anti-Aircraft Corps for foreign service, but finding that corps was no longer sending men abroad he obtained, in January, 1916, a commission in the Army, being gazetted to The Buffs. He was sent to Ireland for training, and was employed in the suppression of the Sinn Fein Rebellion. In June, 1916, he was transferred to The Queen's, and was to have gone to France in September, but was transferred to the Machine Gun Corps, with which he went out to the front in November last. His commanding officer writes: "Though only a short time with us he had endeared himself to all by his devotion to duty and cheerful disposition under very trying conditions." He had no fewer than sixty-five relatives serving their country since the outbreak of war. He was elected a Fellow of the Royal Society of Arts in 1911.

GENERAL NOTES.

GERMAN SHIPPING.—Captain Schroeder, in a lecture before the German Institute of Science of Navigation, stated that since the outbreak of war 152 German ships, representing 452,000

registered tons, had been destroyed by mines or torpedoes; 267 ships, with a cargo capacity of 807,000 tons, had been captured by the enemy and turned to his own use; and 621 merchant ships, of 2,341,000 registered tons in all, were lying interned in neutral harbours. In German harbours are 490 steamships, of a total of 2,400,000 registered tons. This means that 7·5 per cent. of German tonnage is irrevocably lost, 13·4 per cent. is in the hands of the enemy, 39·1 per cent. is in neutral harbours, and 40 per cent. in Germany.

The Influence of Foreign Ingredients on Steel.—An important paper by Dr. J. E. Stead, read at the annual meeting of the Iron and Steel Institute recently, discussed the effect of small quantities of phosphorus, sulphur, manganese, copper and tin on the qualities of steel. Attention is drawn to the need of greater precision in describing experiments on various steels. For example, in recording the results of tests of tensile strength, the dimensions of the test-pieces should be stated, and, in dealing with normalising and annealing, the temperature of heating and the time of cooling to below redness should be recorded. Speaking generally, the deleterious effects of impurities appear to have been exaggerated. Thus the effect of phosphorus within 0·1 per cent. is comparable with that of carbon, and 0·13–0·20 per cent. is desirable to give good machining properties. Phosphorus alloyed with iron also makes the metal less liable to corrosion. While sulphur *per se* may cause "red-shortness" in small quantities, it is actually beneficial provided manganese is also present. Silicon up to 1·5–1·75 per cent. increases the limit of ductility and tensile strength, while copper, in quantities less than 0·5 per cent., has little or no influence on the mechanical properties. Tin, however, in any sensible quantity should be avoided, as it makes the steel difficult to roll, and hard and stiff when heated.

An Electric Bread and Butter Machine.—The American bacon slicer is common enough in grocery stores, but the bread and butter machine, which is of British manufacture, is somewhat unusual. It is designed for operation by a ¼ h.p. direct-current motor, which drives it by a narrow belt passing round the periphery of a large flywheel. There is a large rotary slicing knife, a cylinder containing the butter, and a long trough which holds the loaf. The mechanism provides for adjustments which make it possible to regulate, as desired, the thickness of the slice of bread and the amount of butter which is spread on the slice. Once the mechanism is set for these, the machine will continue indefinitely to turn out slices at the rate of about 3,600 per hour. The butter is evenly spread over the slice, and it is quite immaterial whether the bread put into the machine is new or stale; the makers of the machine state that "new bread is perfectly cut and buttered within two hours of baking." According to the *Electrician*, a large number of shipbuilding works on the Clyde have been supplied with machines.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

January 24.—W. A. M. Goode, Hon. Secretary, National Committee for Relief in Belgium, "Relief Work in Belgium."

January 31.—Miss Ella C. Sykes, "The Work of the Y.M.C.A. in France."

February 7.—Robert Fortescue Fox, M.D., "The Future of British Spas." Sir Thomas Barlow, Bt., K.C.V.O., F.R.C.P., M.D., LL.D., F.R.S., will preside.

February 14.—Lawrence Chubb, Secretary to the Commons and Footpaths Preservation Society, "Highways and Footpaths."

Indian Section.

Thursday afternoons, at 4.30 p.m. (except where otherwise announced):—

January 18, at 4 p.m.—Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., "Between the Tigris and the Indus. The Ben-i-Israel." The Right Hon. Viscount Bryce, O.M., D.C.L., LL.D., F.R.S., will preside.

February 15.—Professor H. Maxwell-Lefroy, M.A., F.E.S., F.Z.S., Imperial College of Science and Technology, "The Indian Silk Industry."

March 15.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

April 19.—

May 17.—Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

January 30.—Octavius C. Beale, Representative and Past President of the Australian Associated Chambers of Manufacture, "Imperial Industries after the War."

February 27.—Alfred Bigland, M.P., "Imperial Assets and how to use them."

MARCH 27.—The HON. FREDERICK W. YOUNG, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced :—

JAMES HARRIS VICKERY, LL.B., "German Business Methods."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time : its National Importance."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

HOWARD LECTURES.

Monday afternoons, at 5 p.m. :—

WILLIAM RIPPER, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m. :—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 5, 12, 19.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 15...Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Very Rev. W. R. Inge, "Christian Mysticism."

Bibliographical Society, 10, Hanover-square, W., 5 p.m. Mr. A. Bolton, "Robert Adam, the Architect, as Bibliographer and Builder of Libraries."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. Marie C. Stopes and Dr. R. V. Wheeler, "The Constitution of Coal." 2. Dr. R. Lessing, "A New Method of Extracting Vaporous Constituents from Coal Gas."

TUESDAY, JANUARY 16...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Professor J. T. Morris, "The 'Lumen' as a Measure of Illuminating Power."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. Forbes-Leslie, "The Occurrence of Petroleum in England."

Statistical Society, King's College, Strand, W.C., 5.15 p.m. Baron A. Heyking, "The Economic Resources of Russia, with special reference to British Opportunities."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Old Brain and the New Brain, and their Meaning." (Lecture I.)

Photographic Society, 35, Russell-square, W.C., 7 p.m. Messrs. A. B. Hitchins and F. B. Gilbert, "A Shutter-Testing Machine."

WEDNESDAY, JANUARY 17...Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. W. L. Nash, "Egyptian Magic."

Meteorological Society, Caxton Hall, Westminster, S.W., 5 p.m. 1. Annual General Meeting. 2. Major H. G. Lyons, "The Winds of North Africa."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. Janet Lane-Claypon, "Principles of Organisation and Administration in Child Welfare."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor Sir Henry Newbolt, "The Poet and his Audience."

Aëronautical Society, at the Grosvenor Gallery, Bond-street, W., 8.30 p.m.

Microscopical Society, 20, Hanover-square, W., 8 p.m. Presidential Address by Mr. E. Heron-Allen, "Alcide D'Orbigny, his Life and Work."

THURSDAY, JANUARY 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. (Indian Section.) Sir Thomas H. Holdich, "Between the Tigris and the Indus. The Ben-i-Israel."

Linnean Society, Burlington House, W., 5 p.m. Professor F. O. Bower, "The Comparative Morphology of the Sorus of Ferns."

Chemical Society, Burlington House, W., 8 p.m. Colonel C. T. Heycock, "Alloys of Copper, Tin, Aluminium, and Gold."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir Walter Raleigh, "The Strength and Weakness of Romantic Poetry." (Lecture I.)

Historical Society, 22, Russell-square, W.C., 5 p.m. Mr. A. F. Sieveking, "Duelling and Militarism."

Numismatic Society, 22, Albemarle-street, W., 6 p.m.

Economics and Political Science, London School of, Clare Market, W.C., 5 p.m. Mr. E. J. P. Benn, "The Organisation of Trades."

FRIDAY, JANUARY 19...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor Sir James Dewar, "Soap Bubbles of Long Duration."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture I.)

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Messrs. A. G. Cooke, W. J. Gow, and W. G. Tunnicliffe, "The Manufacture of Gauges at the L.C.C. Paddington Technical Institute."

SATURDAY, JANUARY 20...Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. R. Hinks, "The Lakes and Mountains of Central Africa." (Lecture I.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—January 12, 1917.

Journal of the Royal Society of Arts.

No. 3,348. VOL. LXV.

FRIDAY, JANUARY 19, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 24th, at 4.30 p.m. (Ordinary Meeting.) W. A. M. GOODE, Hon. Secretary, National Committee for Relief in Belgium, "Relief Work in Belgium."

INDIAN SECTION.

Thursday afternoon, January 18th; The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., in the chair. A paper on "Between the Tigris and the Indus. The Ben-i-Israel," was read by COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

COAL AND ITS ECONOMIC UTILISATION.

By JOHN S. S. BRAME,
Professor of Chemistry, Royal Naval College, Greenwich.

Lecture III.—Delivered December 11th, 1916.

Consideration may now be given to the means which are open to us for the more economical utilisation of our coal, and the natural course will be to deal first with wastage in production. In the past coal-mining has been characterised by the little regard which has been paid to wastage of good coal, often, of course, through financial considerations. The Royal Commission (1905) directed attention to many possible economies, such as those possible through the more extended use of coal-cutting machines, and of plant for the treatment of small coal to enhance its market value.

Many of the losses of coal are unavoidable. Barriers, for example, must be left between adjoining properties, and these often have to be of considerable thickness in the vicinity of old workings, where there is risk from water or foul gases. Barriers between properties will obviously be reduced by mining operations on a larger scale, as, for example, when seams are worked by large concerns, also by amalgamations. Further, large scale operations lead to abolishing irregularities in the boundaries. Then there are barriers in the pits, and pillars left as supports. It may be intended that these shall be worked out, but the cost of doing so, and the crushing the coal undergoes, often prevent this being done.

The Royal Commission (1905) in estimating the coal reserves made allowances varying from 15 to 30 per cent. for coal which had to be left underground, the average deduction from the total coal being 22·7 per cent.

There are unavoidable losses also in winning the coal by reason of the small dirty coal produced; but a great deal of really good coal is often wasted because it does not pay to bring it to bank. If coking is not carried out at the pit, there may be no profitable outlet for such small coal. On the other hand, by proper treatment of small coal, it can be rendered serviceable for such purposes as steam raising—a use to which the introduction of mechanical stokers has greatly contributed.

Large quantities of good but small coal have been left in the worked-out areas, in many cases giving rise to "gob" fires through spontaneous ignition. In cases where such small coal has been recognised as likely to ignite, it has been brought to bank and thrown on the tip.

There has been very considerable extension of the use of coal sizing and washing plant of recent years, but even now we are far behind Continental practice. By the use of such plant much small coal which was at one time not marketable at a profit now fetches remunerative prices. The use of such coal for steam raising naturally conserves for special uses the better-sized coal.

Then, again, where the coal was of a suitable character, coking of the small coal became general, the earlier ovens being of the very wasteful beehive type; but it must not be forgotten that, although these ovens are extremely wasteful and the "bogey" of fuel economists, they really contributed to economy in production, although such contribution was far less economical in itself than it need have been. It is a fact, however, that large quantities of coal which would never have been considered worth bringing up but for the introduction of the beehive ovens have been converted into valuable fuel.

In some districts, however, the waste of small but nevertheless good coal is still tremendous. Professor Henry Louis has stated that in the Nottingham coalfield he has seen coal loaded into the tubs with forks having tangs $1\frac{1}{2}$ in. apart, all the coal which these forks did not raise being thrown into the "goaf."

Another contributing factor to the waste of small coal has been payment based on large coal produced—a system devised to encourage the production of a higher percentage of large coal. In this it doubtless had the desired effect; but although less small was produced, such small could not be profitably marketed if it had to bear the same charge for working.

Any system which reduces the quantity of small coal produced in working, providing it is not handicapped by such considerations of payment, will clearly be on the side of economy. By the use of coal-cutting machinery, the advantages of which were emphasised by the Royal Commission (1905), less small coal is produced, and it is often possible to do the cutting in the underlying strata instead of in the coal itself. Thin or hard seams which cannot be worked profitably by hand can often be won with machine cutting.

Most cutting machines are in use in the Yorkshire and Midland coalfields; in 1913, 2,892 of these machines were in operation in this country.

There is one and a very reprehensible practice which leads to waste of coal which should be utilised, and that is the working of only the best seams, or even the best part of one seam, where it is fairly thick and of two kinds. Working of only the best seams often leads to such damage of the less valuable coal that it afterwards does not pay to win it. As an example of the waste of coal through working part only of a seam, in the Mines Report (1910) it is stated that in places the valuable Barnsley seam is worked only for the hard lower portions, the top softer coal being rejected. This soft coal is often 4 ft. thick, and it was estimated that some 40 per cent. of the whole thickness of the seam was left in the pit. Beyond its softness, it is just as good as the hard coal.

With the introduction of coking plants, where suitable coals are worked, of briquetting plants, as in South Wales, for the treatment of harder coals, and of sizing and washing plants, the amount of small coal wasted has been very materially reduced, and the increased price for such prepared coals has proved an important factor in the economy of coal.

By washing coals, not only is the earthy matter greatly reduced, but also the quantity of pyrites, which lowers the sulphur content of the coal (or coke)—an important consideration for metallurgical uses. The picking, sizing and washing, moreover, effect the removal of such dirt as is inevitable when cutting machines are worked in the underlying strata, and in this way indirectly contribute to economy.

At most modern collieries the arrangements for handling the coal, for picking and sizing, and for washing are very complete; but there is still a lot of fine dust from screens and "smudge" from washing plants to the profitable utilisation of which attention might be directed. The former would appear most suited to dust firing if properly treated.

The quantity of coal consumed in working a pit often represents an unduly high proportion of the output. True, it is often very poor quality coal which is so used, and because of the difficulty of finding a market, and because its quality is so low that it cannot carry transport charges, there has been little incentive to economy, which would often mean incurring capital charges for more efficient power plant. It is not unusual to find reciprocating engines of very low efficiency in use at pits, non-condensing engines are not uncommon, and steam is often carried considerable distances.

It is difficult to estimate the waste which occurs at the pithead, or what proportion of the output is used for the actual colliery operations. The British Association Committee hopes to collect some reliable data on the point. Professor Henry Louis has estimated that the average consumption at the pit is 7 per cent., equal to the large total of 20 million tons.

Where operations are on a sufficiently large scale, gas-producer plant has been installed with considerable economy. Not only is power

obtained at a low cost, but sulphate of ammonia is recovered, and in some cases fuel so poor as to be useless for steam raising when burnt under boilers can be gasified, so that saleable coal which would otherwise be used at the pit comes on the market.

Where groups of pits exist the installation of a central gas-producer plant, from which electrical power could be distributed to the individual collieries, would in many cases be a sound procedure. Again, in the North-East Coast power scheme, collieries generally take their power from the system, and this has led to great savings.

Professor Henry Louis, in the discussion on the Fuel Economy Committee Report at the British Association in September last, stated that by stopping colliery waste the saving to be effected would be as great as by all other methods of economising fuel put together (see *Engineering*, September 22nd, 273).

Turning now to economy in use, it was shown in the first lecture that some 60 million tons of coal are employed in factories, and the bulk of this is for power production. It can be stated that of the potential heat units in this coal we certainly utilise less than 10 per cent.

With our present knowledge of methods of getting power from coal, the best utilisation we are likely to effect (by gasification and use directly in gas-engines) will be about equal to 20 per cent. of the available energy.

From the Census of Production (1907) the power developed in the United Kingdom and the means of generation are :—

10,578,475	Horse-power developed.
680,177	By internal-combustion engines.
117,907	By water.

Considering next the relative efficiency of power plants, taking the over-all efficiency, *i.e.* boiler (or producer) and engine, the following figures are approximately correct :—

Type of Engine.	Approximate Over-all Efficiency.	Equivalent lbs. of Coal per h.p.
Steam.		
Small reciprocating, non-condensing	5	4–5
Large multiple expansion, condensing	6–7	3–4
Large turbine sets	15	1·4
Producer Gas	20	0·9–1·1
***Oil.* Diesel type**	30–33	0·45-0·5 (oil)

These figures are average figures for good practice, but with steam plants very frequently much lower figures are obtained through faulty operating.

Economy in operating can be obtained by more attention to combustion. The losses through large excess-air supply and the method of checking these losses by the record of carbon dioxide in the flue gas have been dealt with in a previous lecture.

Further, in the majority of cases coal is purchased with but little regard to its heat value. It is generally recognised now that the industrial value of coal for heating is broadly proportional to its calorific value, and now purchase based on the calorific value, payment being made on a sliding scale, is generally recognised as sound, and has already been adopted by several large concerns in this country. Once the producer is convinced that all the benefits are not to be on the side of the consumer, that the supply of coal of better quality will bring a correspondingly better price, the very natural opposition to such a method of purchase on the part of the seller will disappear.

The combination of the purchase of coal on a scientific basis with scientific control of combustion leads to very considerable economies, and for some years I have advocated the employment by all large coal consumers of trained fuel experts—a course which would lead to savings far greater than the remuneration of the expert. Some large consumers have already adopted this plan.

Post-graduate courses of instruction in such work are carried out at the Imperial College of Science and Technology and at other technical colleges. In the evening classes held under my direction at the Sir John Cass Technical Institute over ninety students have undergone instruction in the period 1909–14: most of these were either engaged in the control of power plants or in industrial operations where coal was an important factor.

In the whole scheme of coal economy it will obviously be desirable to employ the form of plant which gives the highest thermal efficiency, for by such plant the lowest fuel consumption will be attained; but many other considerations besides thermal efficiency will be taken into account. It has been shown above that the gaseous fuels derived from coal used directly in gas engines give a higher thermal efficiency than any form of steam plant. It was to gaseous

fuel that the Royal Commission (1905) looked for the realisation of enormous economies in coal consumption. On the computed consumption of from 40–45 million tons employed in factories, it was estimated that a saving of 20–30 million tons was possible. On the total industrial consumption of 143–168 million tons, the estimated possible saving was 40–60 million tons.

Since that date, however, the steam turbine has developed and, although inferior as a heat engine to the gas engine, has proved a more serviceable power unit for large-scale power production than the gas producer and gas engine.

With the erection of the large Mond gas plant at Dudley Port, in Staffordshire, and the distribution of power gas at a cheap rate throughout the district, great hopes were raised that similar plants would be installed in other industrial districts. The cost of distribution of gas of such low calorific value must be high, very large mains being required. Further, according to figures by Mr. Humphrey, it would appear that the heat units in the gas distributed represented rather less than 50 per cent. of the heat units in the coal gasified. Further schemes on similar lines have not developed, and power distribution on a large scale will follow on the lines of electrical generation.

For power production and distribution as electrical energy on a large scale, the turbine has practically completely supplanted the gas producer in the opinion of engineers. For one thing, the largest gas-engine units are far smaller than even moderate-sized turbine sets, the latter now running to 25,000 k.w., and even much larger units in America, and economy in every way results from the employment of the largest possible units; again, the lower cost of a steam-turbine installation, general economy in use and greater reliability have convinced engineers of the advantages of turbines as a whole over the gas plant, in spite of the higher thermal efficiency of the latter.

Raw coal is, however, almost invariably used for the generation of the steam, so that its valuable nitrogen is entirely wasted, together with other by-products. This has led to the suggestion that coal should be gasified and the gases used for boiler firing. In such practice the producer efficiency would not exceed 75 per cent., and the efficiency of the boiler under gas firing would probably be about 70 per cent., giving an efficiency in all of about 52 per cent. (not including the engine). On the other hand, a good boiler plant with coal firing would give an efficiency of 80 per cent. Allowing, then, that with the producer and gas firing an efficiency as high as 55 per cent. was obtained, there is a difference of 25 per cent. in favour of coal firing; and this would obviously have to be made up by the value of the by-products, which could only be produced in a plant much more costly in the first place, carrying, therefore, higher capital charges — a type of plant admittedly more costly to operate, and requiring far more attention than a machine-stoked boiler installation.

It would not pay, therefore, to use coal in this way; either the coal must continue to be burnt without treatment, in the usual way, or if gasified used directly in gas engines, the superior efficiency of which would compensate to a considerable extent for the poorer efficiency of the gas-steam plant. Here, again, the difficulties of large gas units come into the question.

Producer gas plants with gas-engines, however, have their proper sphere in the economy of coal, and have contributed very largely to economy. When required for furnace heating as well as power, gas plants are commonly installed, and as in such cases large quantities of gas have to be produced, recovery of by-products pays. In moderate-sized power plants, again, the gas producer with gas engines is economical, the absence of by-product recovery leading to simplification of working and cost of both installation and operating.

Another highly important point is that a class of coal totally unsuited to use for steam raising can be employed in a producer, so that good steam-raising coal is economised.

The introduction of suction gas plants, practically automatic in their action, except for the introduction of fresh fuel at intervals, and giving a very low fuel consumption of almost 1 lb. per b.h.p., has also been a great advance, because such plants have almost invariably been installed in place of moderate and small-sized steam plants, the latter being notoriously inefficient as power units.

Coal gas has become a fuel of considerable industrial importance both for heating and power production. Its applications for industrial heating are most wide and varied—on a comparatively large scale it is employed for furnace heating, such as muffle and other furnaces for the treatment of steels, and for metal melting, where fuel costs have been very materially reduced, besides advantages arising from reduction of labour, reduction of melting losses, and of cost of crucibles. In competition with other

forms of heating, coal gas has been selected and installed at the Royal Mint for all melting purposes.

In many of our principal towns the price of coal gas is so low that, combined with its efficiency, it offers many advantages both for power production and heating. In many towns the special price for such purposes lies between 1*s.* and 1*s.* 6*d.* per thousand cubic feet.

Turning from the use of coal and its products for industrial purposes, brief consideration may be given to their use for domestic purposes. It was shown in the first lecture that this domestic consumption probably amounts to 35,000,000 tons per annum, and in addition to this it must be remembered that a very considerable amount of coal gas and coke, and some electric energy, derived from coal, are also employed.

In the use of raw coal in the domestic grate we have at once perhaps the most comfortable form of heating and the most wasteful it is possible to devise. A table which I may quote from Professor Lewes gives the distribution of heat units from the coal fire as :—

Much improvement in efficiency may be looked for in the construction of better grates. Mr. A. Vernon Harcourt, F.R.S., recently discussed this question before this Society (*Journal*, 1915, LXIII. p. 570), and pointed out that our grates were fundamentally wrong in not giving horizontal radiation. He described his own form of grate, which possessed the great advantages of maximum radiation surface, this surface being vertical, and therefore highly efficient. Moreover, it burns coke perfectly, and so a hot, efficient and smokeless fire is obtained.

We must recognise also the great advances which have been made in the application of coal gas for domestic purposes, for heating, for cooking, and for the maintenance of hot water in the system usually dependent upon the closed range. Mr. F. W. Goodenough has dealt with this subject in Cantor Lectures (1913). It is sufficient to say here that since that date there has been further improvement in stoves and hot-water appliances. In some of the former a radiation efficiency of over 50 per cent. has been attained. It is no wonder that heating by coal gas has made marked progress, to the

In gas—5 cubic feet at 570 B.Th.U.	2,850	Lost 81 per cent.

" grate and ashes	265	
" radiant heat from coke	2,485	Used 19 per cent.
" " " flame	190	
Total heat units per lb.	14,000	

improvement of our atmosphere and the reduction of fogs, to say nothing of the purely domestic advantages in the reduction of dirt, dust and work. It is equally or even more true that the same advantages arise from electricity; but, except where current is much cheaper than in London, the use of electricity for general heating is too expensive.

Another very important point is that the open fire is notoriously a bad smoke producer. It has been estimated that 70 per cent. of the smoke over towns, other than large industrial towns, is due to domestic fires. It is universally admitted that the abolition of this smoke would be a great blessing, and it cannot be gainsaid that very considerable reduction has resulted from the great extension of the use of gas for heating and cooking.

But the open grate is unlikely to be generally disestablished in popular favour, partly perhaps because of fancy and custom, partly on the good grounds that for living rooms heated air without a source of radiant heat also is unsatisfactory, and largely because, owing to the great natural sudden variations of temperature, systems of heating by closed stoves or hot pipes are not suited to the conditions. It remains, therefore, either to find a more suitable fuel which is smokeless, such as coke, or to extend further he use of coal gas and electric heating.

The utilisation of gas coke for domestic purposes provides an important outlet for the surplus from the gasworks, and the demand at the present time is very large, the high price of coal and the difficulties in securing delivery being contributing factors. While admittedly imperfect in many ways, it is not only a useful fuel but a smokeless one. In the ordinary way of wet quenching the coke often carries an undue proportion of water, which detracts from its value as a fuel in the open grate; but systems of dry quenching are now frequently employed. Other factors against coke as a fuel are the frequent high ash content, difficulties of ignition,

and the necessity for the use of a proportion of coal with the coke in most open grates.

Because of these disadvantages great hopes are placed upon coke obtained by carbonisation at temperatures of about 500° C. instead of at temperatures of over 1000° C., as in gasworks practice.

"Coalite" was a fuel of this type, and there can be no question but that low-temperature coke is an almost ideal smokeless fuel. Such coke contains from 8 to 10 per cent. of volatile matter, which enables a fire to be kindled without the aid of raw coal, and perfect combustion to take place in open grates. It is to low-temperature coke that most enthusiastic advocates of the prohibition of the use of raw coal for domestic purposes are turning for a solution of the problem of a smokeless domestic fuel, and on the successful production of which they are relying for the hoped-for legislation.

But, as Mr. Butterfield has pointed out, great as are the advantages of such cokes, they suffer from some inherent disadvantages of all coked coal, one being its bulk in relation to heat units, giving an unduly high stowage value, a matter of some importance, reducing as it does cellar accommodation in terms of heat units. Most of these cokes have, up to the present, been also unduly "tender," so that they do not stand well in transport. Unless backed by legislative enactment, producers of these soft cokes will have to sell at an appreciably lower price than coal—the appeal of smokelessness and quality will be to the few otherwise—but there seems little doubt but that this can be done.

Passing from the consideration of these cases where economy is possible in the ordinary ways of employing coal, or fuels prepared from coal, there are two very important industrial operations where great saving is possible, even although considerable progress has been made in reducing this waste. These are the waste of heat in blast-furnace and coke-oven practice.

The old open-throat blast furnace is almost a thing of the past, but even where the combustible gases from the furnace, not required for heating the stoves which provide the hot blast, are used for power production, this utilisation of the surplus is often carried out in an uneconomical manner. Often this is because there is more than sufficient for the actual operations of the plant and there is no outlet, in the absence of any collective waste-heat scheme, for the surplus power which the gases are capable of giving.

The available surplus power from blast furnaces amounts to a very large figure. Approximately, for every ton of iron produced, 150,000 cubic feet of gas of a calorific value per cubic foot of 90 to 100 B.Th.U. are obtained. After heating the blast stoves and operating the plant with gas-driven engines, a surplus of 65,000 cubic feet may result, this being equivalent to an output of about 650 b.h.p. In 1913 there were 337 blast furnaces in operation, the output of pig iron being 10,260,315 tons. It would entail the expenditure of a large amount of capital to put many of these plants into a condition for the profitable use of the surplus gas; again, until collective systems of power distribution are established in the districts, means are not available for the distribution of the energy; but such enormous waste of energy is taking place that its proper utilisation is a matter of great importance. At one large iron and steel plant, where a modern system of utilising the gas was installed, on four furnaces it was estimated that the weekly saving in fuel was equivalent to £1,000.

The second case of waste of available energy on a large scale is also closely connected with the iron industry, namely, the waste in many coke-oven plants. The beehive ovens originally put down for the conversion of much small coal for which there was no remunerative outlet were extremely wasteful, both in giving a lower yield of coke and in waste of heat and valuable by-products. By coking in suitable large chamber ovens, and utilising the regenerative system by which the hot gases on leaving the flues are made to impart their heat to the air supplied for combustion, it is found that a large proportion of the gas produced is available for purposes not connected with the actual coking operation. In addition, the yield of coke from a given coal is materially increased, and valuable by-products, identical with those from ordinary coal-gas manufacture, are recoverable.

The surplus gas available per ton of coal carbonised is about 5,000 cubic feet, and its calorific value about 550 B.Th.U. per cubic foot, so that a coke-oven plant carbonising 400 tons per day and giving the above amount of surplus gas will, with the consumption of 21 cubic feet per b.h.p., operate a power plant with an output of 4,000 b.h.p. per hour.

There has been a fairly rapid replacement of the old wasteful beehive ovens in recent years (of which the output of sulphate of ammonia shown in Fig. 3, p. 155, is a comparative measure); but in 1913, of the 20 million tons of coal

converted to coke, about one-third was worked in beehive ovens, and 13,000 of these were still in use. In 1914 the number had been reduced to 9,210.

Surplus coke-oven gas is being utilised as a source of power for the supply of the collieries, or in connection with a "waste-heat" scheme, in admixture with producer gas for steel making, and as supplementing the supply of coal gas in the neighbourhood. On the Continent and in America large quantities of coke-oven gas are used in this way. Arrangements have recently been made by the City of Leeds Gas Committee for the daily delivery of one million cubic feet of coke-oven gas from the plant at Middleton, this being about one-fifteenth of the maximum daily output of coal gas. Provision is made for delivery in regular quantities each hour, and the quality of the gas is checked by recording gas calorimeters.

Where coking plant is able to deliver such gas to a neighbouring gas company very considerable economy in coal is possible; but because of the statutory obligations of gas companies to maintain a constant service, it will still be necessary for most illuminating gas to be made specially, as a coke-oven plant is dependent on the iron trade for its activity, and, unless it is certain that a plant can be kept in operation, a gas concern largely dependent on it might be placed in serious difficulties.

Great as savings would be which can be realised by individual action, they are small as compared with what might be realised by collective action throughout a district.

Through electric generation and distribution every advantage may be taken in most of the big industrial districts of Great Britain of the principal supplies of waste heat, such as from coking plants and iron furnaces. The extensive scheme which has been in operation on the North-East Coast for some years is an object-lesson in what can be accomplished; but even here conditions are not such that the maximum economy is possible.

The district is one in which collieries, coke ovens and blast furnaces are operated in large numbers, and although some local utilisation of waste heat in individual cases is possible—for example, from a coking plant to the colliery —much greater advantage lies in pooling the waste heat to a central electric distribution system.

The underlying principle is to have a uniform collecting and, therefore, distributing electric system. Waste heat from coke-ovens, blast furnaces and exhaust steam from blowing engines (through low-pressure turbines), is utilised continuously at maximum electrical output, and the supply supplemented as necessary from steam-operated turbine sets at a limited number of stations.

Power is actually taken from producers and returned to them in such amounts as individually required at a cheaper rate than they could actually produce at, thereby leading to great savings on the part of the producers, who are spared the expenses of stand-by plant which would be required without this co-operative principle.

In this district at the commencement there were six coal-fired generating stations and five waste-heat stations. Now there are eleven waste-heat stations and two main steam generating stations. Several small uneconomical stations have been closed.

The area covered by the scheme is 1,400 square miles; the length of the district (north to south) is seventy miles; and the present total horsepower generated, 343,000. Great savings in the coal consumption of the district (especially for collieries) have resulted, and the cheap current has practically abolished the individual generation of steam power; collieries with an output of over 20 million tons now depend on this supply, and show a saving of about 75 per cent. in coal consumption (equal to one million tons of coal); the suburban railways are supplied with electric power for eighty miles of single track; heavy freight haulage is carried out on fifty miles of track; tramway systems are supplied with current. In addition, lighting is provided in towns with an aggregate population of 700,000.

Another important feature is the development of new industries, notably electro-chemical.

One essential point in such a scheme is to maintain a high load factor, which is only possible when there is a great diversity of use for electricity throughout the whole day.

The North-East Coast scheme has gone some way towards the realisation in one district of the prophetic vision of general electrification of the country with which Mr. de Ferranti startled the country in his Presidential Address to the Institution of Electrical Engineers in 1910.

Mr. de Ferranti estimated that by conversion of all coal used for power into electrical energy in the producing area, 60 million tons of coal would do the work of 150 million tons at present used, providing a load factor of 60 per cent. could be maintained. With this saving in coal

there would accrue also the advantages of reduction of coal consumption, abolition of labour in transporting coal, the abolition of smoke and dirt, and the provision of vast amounts of sulphate of ammonia which was to render England independent of imported food supplies.

Such visions are by no means impossible of realisation, but there are many obstacles to be faced. No such system is practicable without unification—this is the essence of success, and one great difficulty is the present diversity of the systems of electric generation and distribution, which is so great that any comprehensive scheme would involve the scrapping of a large number of still efficient machines, and the large sums of money represented by municipal concerns and the investments of the public in electric power and light companies, have to be considered, together with the difficulties from the monopoly of rights of distribution in the districts. Before the expense of building up could be met large sums would be called for in compensating for these investments and monopoly rights, and generally arranging satisfactory amalgamation terms.

Some steps in the direction of more systematic distribution have resulted from present conditions, the Board of Trade having recently issued a circular in reference to the linking up of generating stations, and in certain districts this has been accomplished, one or more generating stations carrying the load in rotation, others remaining as stand-by stations. This linking-up will be further extended as the committees which have the matter in hand make the necessary arrangements, and considerable economy in fuel will result.

When we consider that our railways in 1913 carried 210 million tons of coal, and consumed a further large quantity in doing so, and that at the end of the journey the large part used for power production did not give a greater return than some 10 per cent. of its total heat units, the advantages to be gained by the use of the coal at the point of production, and distribution of its heat energy in the form of electricity at much higher efficiency, are obvious. But the distribution of electricity to areas far removed from those centres favourable to its production will probably be long deferred, as will also the general electrification of main railway lines, as there are many difficulties to be overcome. If, however, as many hope, our waterways are developed as a national concern after the war (a useful method of finding employment for the large numbers who will be returning to civil life) the introduction of electric haulage would be possible, and such a system would be of enormous benefit in the transit of heavy merchandise and a useful outlet for power from a large producing district.

Without going so far as a general power scheme over larger areas than the great industrial centres, there can be no question that enormous economies are possible in such areas because existing conditions are generally favourable. There has been a natural concentration of industries and population in the vicinities of our coalfields; the principal sources of waste heat—iron smelting, with its complement, coke manufacture—have developed naturally in the same areas. There is the large demand for power for industries, for locomotion, and for the general supply of heat and light to a large population.

But admitting the great advantages of electricity for distribution generally, especially over considerable distances, as compared with coal gas, the general use of coal gas and the value of its by-products place it in too strong a position to be overlooked as a most important factor in such a scheme. It has already been seen how coke-oven gas as supplementing coal gas does lead to economy in coal. The utilisation of the large quantity of coke available after all works requirements are met for the generation of power by gasification and the use of the gas in gas engines would enable the large gas concerns to be profitably linked in. Not only would a better economy in the use of the coke be obtained, but a large proportion of the nitrogen in the coke could be rendered available as a fertiliser.

Further, it is almost universally admitted that sooner or later low-temperature carbonising schemes for the production of a smokeless domestic fuel, which would have decided advantages over gas coke, will prove successful, and the development of such schemes should bring them also naturally into the one big scheme applicable to the district.

In the latest developments of these schemes arrangements are being made for the gas produced to be mixed with producer gas, obtained from cheap slacks and "smudge," and utilised for power production.

Such co-ordinated schemes for the better utilisation of our coal supplies will necessarily develop in the coal-producing districts. Here waste heat would be available from coking and blast-furnace plant; coke ovens might also

supply local gas undertakings with a proportion of their gas; from the gasworks power would be supplied to the system through the surplus coke; producer-gas plants would work on a large scale on the small and low-grade fuels at stations near the pits; the domestic fuel plant would provide the smokeless fuel for the grates (which would be supplemented by gas heating), and contribute through its gas to the power production. A few coal-fired plants with large units would serve to make up production to the full output, as required.

With such a scheme in operation there would be an enormous reduction in the amount of good coal used for steam raising. Although raw coal would still be utilised—a proceeding very reprehensible to some people, although capable of justification in a large number of instances—a very great addition would be made to the valuable by-products, sulphate of ammonia and tar; at the same time an all-round large reduction in the total coal used would be achieved.

One very important consideration arises in respect to the tar produced. Chemists are so impressed with the great value of tar as a source of raw material for industries of great importance that they are apt to overlook the possibility of overproduction, which would relegate much of the tar to utilisation for purely fuel purposes. Even in 1909 the price of tar was as low as 11*s.* per ton, and benzol was 6*d.* per gallon. The quantity of tar produced at present is approximately:—

	Tons.
From 17,000,000 tons coal at gasworks .	850,000
,, 13,000,000 ,, ,, coke-ovens .	650,000

In the near future practically all metallurgical coke will be produced in recovery plant, yielding another 350,000 tons. The position will certainly be, when the present big war-demand for tar products ceases, that there will be considerable overproduction in relation to the quantity normally necessary to furnish finished tar products.

The high-temperature tar will amply supply all raw material for special industries (benzol, toluol, carbolic acid, etc.), whilst the low-temperature tar, because of its greater fluidity, low free-carbon content, and the high yield of low boiling constituents suitable for motor spirit (but not so suitable for the production of the purer benzols and toluols as the high-temperature tar, by reason of the high proportion of other hydrocarbons), will find its use for fuel purposes. After distilling the lighter spirits off, the heavier oils will be soda washed to recover the high proportion of cresylic acids present, the residual oils being suited to use in internal-combustion engines of the Diesel type.

London is in a special and unique position as regards such a general-power scheme: it is far removed from coal-producing districts (at least, until there has been considerable development in Kent); it has an enormous population and big demands for power, although no large individual demands which compare with the big industrial concerns in the North; enormous demands for lighting and domestic heating.

The electricity supply system is simply chaotic, and many of the generating plants far too small for the best efficiency to be realised, as the following table, compiled from data in the valuable report furnished to the County Council by Messrs. Merz and McLellan in 1914, shows:—

Electricity Undertakings, Greater London, 1912.

Number of authorities	70
Total capital outlay	£25,997,399
Expenditure—plant and machinery	£8,059,601
Plant installed	307,338 k.w.
Generating stations (not including 9 traction)	70
Average size of units	632 k.w.
Number of frequencies	10
,, voltages, as distributed	24

Linking-up of stations and systems would, therefore, be very difficult and in many cases impossible, and to attain unification a tremendous amount of alteration would be involved; but the advantages to be gained by so doing, enabling, as it would, a considerable number of the least efficient stations to be closed, are evident.

Waste heat is not available in the London area, and current would have to be generated at large stations situated below London, necessarily on the river-side, so as to secure the advantages of sea-borne coal and ample water supply. For the most efficient scheme I feel convinced that the gas companies and future low-temperature carbonising concerns will have to supplement the directly generated current, the former being linked in by utilising surplus coke in producers and the gas in gas engines coupled with generators, the latter through their surplus gas, to be mixed with poor producer

gas (possibly the coke gas referred to). The gas companies already have their distributing system and market for gas; the low-temperature coke will find the best market in the country at hand.

In this way three important concerns, which would handle coal as their main raw material, could be linked up through the medium of the future uniform system of electricity distribution in the metropolis to the very great advantage of the community, providing cheap electricity, smokeless fuel, and retaining coal gas with its many advantages.

The spirit of aloofness and competition between gas and electricity might well be buried beneath the erection of a comprehensive power scheme for London and the surrounding districts.

Errata.—In Lecture II., in the table of Products from Crude Tar at the foot of p. 156, Toluene should be 0·6 per cent., and Phenol should be 0·2 per cent.

ANNATTO IN PORTO RICO.

Until the European war curtailed available sources of dyestuffs, the market for Porto Rican annatto was very limited. In the fiscal year 1913–14 there was exported 211,886 lb., valued at £2,753. The influence of war conditions began to be apparent late in 1914, when exportations rose to 337,299 lb., valued at £5,564. Since then the increase has been considerable in both quantity and price. Before the abnormal conditions annatto sold as low as 16*s*. 8*d*. to 20*s*. 10*d*. per 100 lb. At present it commands 54*s*. 2*d*. to 62*s*. 6*d*., according to quality.

According to a report by the United States special agent in Porto Rico, the supply of the product is extensive, as the tree grows wild. The collection of the seeds, which constitute the "annatto" of commerce, affords employment and a source of income to country folk, to whom any opportunity for earning money is a considerable boon.

The seeds of the bush or tree *Bixa orellana* are known commercially as annatto. The seeds yield a yellow colouring matter which has been employed in dyeing silk, cotton, and wool. The colour is somewhat fugitive. There is a widespread use in colouring confectionery, butter, cheese, sauces, varnishes, lacquers, and the like. The local name is "achiote."

If the present profitable prices continue, it is probable that the shrub will be planted on a large scale. *Bixa orellana* bushes a year and a half old yield, it is stated, from one-half to one pound of annatto. This amount increases as the plant becomes older.

EFFECT OF KELP HARVESTING ON FISHES.

A preliminary report of observations made to determine the effect of kelp harvesting upon fishes has been submitted to the United States Bureau of Fisheries. The observations were made between Point Loma and La Jolla, in the vicinity of San Diego, California. Evidence of the presence of fish eggs on the kelp was sought. In the case of harvesters that grind the kelp as it is cut such evidence, of course, is not available; but some harvesters do not grind the kelp while cutting it, and in such cases the opportunity was afforded for making the desired observations. No evidence of eggs, fish, or crawfish larvæ could be found. On the kelp beds the leaves were examined to a depth of 8 or 10 ft., and the specimens of molluscs, crustaceans, worms, hydroids, etc., collected. Some small fish were taken, but these were not the young of fish suitable for food, since they were mature at 1 in. in length. No fish eggs could be found.

Although three harvesters had been working on this bed for more than three months, the amount of kelp at the surface of the water had not decreased appreciably. It is said that if the harvesters begin at one side of the kelp beds and cut clean as they go, the first part will have grown again to its natural condition before the whole bed has been passed over.

While the preliminary observations in this region afforded no ground for suspecting that the harvesting of kelp is injurious to important fish or shell-fish, the Bureau intends to continue the investigation.

CUTCH PRODUCTION IN BURMA.

The demand in the United States for crude dyes is being met, in part, by increased shipments of cutch from Burma. In 1915, 1,234,140 lb. of cutch were exported, in contrast with 237,440 lb. in 1914.

In the manufacture of cutch no scientific process is employed, the industry being carried on exclusively by natives. It is obtained from the *Acacia catechu*, the trees being felled while green, the bark taken off, and the timber chopped up and boiled in large cauldrons. The resultant liquid is drained off and solidifies as it cools. In the better qualities of cutch only the heart-wood of the tree is utilised.

It appears from a report by the United States Consul at Rangoon that cutch is brought to the market in several forms, the three principal ones being: (1) Tablets—small rectangular blocks weighing from 1 lb. to 2 lb.; (2) blocks—more or less square blocks weighing from 28 lb. to 56 lb.; (3) baskets—a soft cutch of a thick consistency, not so firmly congealed as the other two qualities. The quality differs in the three

forms in which cutch comes to the market. Tablet cutch is the best quality and basket cutch the lowest. Block and basket cutch usually contain more impurities than tablet cutch, but in recent years a larger business has been done in basket quality than in the other two, probably because basket is the cheapest of the three. On arrival in Rangoon the cutch is packed in wooden cases (usually containing 1 cwt. net) and is then ready for export.

Cutch trees are found throughout the whole of Burma, but the question of transportation makes cutch-boiling unprofitable in many districts. Licences for cutch manufacture are granted annually by the Government, and the industry is more or less of a stand-by to the population in seasons of bad harvests. The Burmese Government increases or reduces the number of licences as necessity indicates. The principal producing districts in Burma are Prome, Thayetmyo, Myingyan, Minbu, Pegu, Yamethin, and Pyinmana.

Cutch is used largely as a dye, but in addition to this it is employed in some countries for tanning and as a preservative. In Burma fishing nets and sails are steeped in it to preserve them from the action of sea-water.

IRON ORE IN SIBERIA.

The iron deposits in the basin of the River Telbess, right tributary of the River Konduma, flowing into Tom River, opposite the city of Kuznetsk, Siberia, have been known since the last century, but not until recently was the region surveyed. In 1913, according to a report by the United States Consul at Vladivostock, the region was turned over by the Crown Land Administration to the Kuznetsk Coal Mine Joint Stock Company, which undertook a careful study of the district with the view of establishing a large iron foundry and works.

Professor P. P. Gudkoff was engaged to do the work, and some of the results are already published. Over ten independent iron deposits were discovered in the region. The main deposit is situated on the right bank of the Telbess River, some five miles from its influx into the Konduma River. It is of an eruptive nature, and consists mainly of granodiorite, quartz, porphyrites, and melaphyre, with secondary strata of crystalline limestone, hornblende, slate, etc. The normal sedimentary strata were discovered only to the north of the region, where the Telbess iron region is separated from the Kuznetsk coal region.

The volume of ore uncovered at the Telbess deposit proper amounts to 3,611,412 tons of 58 per cent. ore and 3,069,700 tons of poorer ore, and at the so-called Temir-Tau deposit to 7,222,824 tons of 54 per cent. ore and 1,305,706 tons of poorer ore. Studies of other deposits of the region in 1915 indicate that the total deposit amounts to over 27,000,000 tons of ore.

THE MARODEM OR VEGETABLE WOOL OF HAYTI.

There are two varieties of kapok fibres to be found in Hayti, both products of trees of the Eriodendron family and both of good quality. The local names for the fibre vary according to the locality; "marodem," "cotton mapou," and "cotton noir" are those most commonly used.

Kapok is fairly abundant all over Hayti, but no commercial use has been made of it. The natives sometimes stuff pillows with it, and occasionally mattresses, but this is about the extent of its utilisation. Indeed, all over the West Indies it is little used and has no fixed market value, except in Cuba, where it is a well-defined article of local trade, and where considerable quantities are bought from the Dominican Republic.

In a report calling attention to this fibre, a special agent of the United States Department of Commerce says that of late some interest in this substance has been taken in the United States, and it is being advertised under fancy trade names as a new discovery for life preservers, cushions on steamers, pillows, and the like. As filling for mattresses it is stated to be an ideal substance, being exceedingly light, absolutely sanitary, and possessing such resilience that even after long use it does not lump or pack. As a quilting material for bed coverings it equals wool in warmth and excels cotton in softness and lightness. For dressing gowns, smoking jackets, and other padded garments it has much to recommend it. For upholstery it is superior to most materials now in use.

Kapok is used in England to some extent in the manufacture of hats, and certain of the longer varieties are mixed with cotton to impart a silky lustre to fabrics. The regular kapok, however, has too short a fibre to spin. It is extremely inflammable, and this is its chief drawback. If the fibre could be so treated with chemicals as to eliminate this dangerous quality it would be very much more valuable.

OBITUARY.

Frank Debenham.—Mr. Frank Debenham died at his residence in Hampstead on January 15th, in his eightieth year.

He was the son of Mr. William Debenham, whom he succeeded in the firm of Messrs. Debenham and Freebody. He was chairman of Debenhams (Limited) from 1905 to 1912, and remained a director till 1914, when he retired.

For many years he took an active interest in municipal affairs. He stood as Progressive candidate for West Marylebone at the first County Council election. He was defeated on that occasion, but in 1889 he was appointed by the Council to represent the borough as Alderman, and he retained his seat for six years. He also

stood as Liberal candidate for Cheltenham in 1892, but was defeated. He served on the board of management of Middlesex Hospital, was a director of the Westminster Life Assurance, and till his death remained a director of Y. Redmond et Cie, of Paris.

He was elected a member of the Royal Society of Arts in 1888, and occasionally took part in the discussions.

Colonel Frank Griffith, V.D.—Colonel Frank Griffith, of the firm of Messrs. W. P. Griffith & Sons, Ltd., printers, of Prujean Square, Old Bailey, died on January 4th at the age of fifty-five. For many years he commanded the 2nd Kent Volunteer Artillery, now known as the 4th London (Howitzer) Brigade, Royal Field Artillery, and he contracted pneumonia whilst on duty as second in command at Biscot Camp, Luton. He was a former Mayor of Bromley, where he lived; Chairman of the Catford Conservative Club; and President of the Kent County Football Association. He was elected a member of the Royal Society of Arts in 1892.

NOTES ON BOOKS.

A Naturalist in Borneo. By the late Robert W. C. Shelford, M.A. Edited with a biographical introduction by Edward B. Poulton, D.Sc., LL.D., F.R.S. London: T. Fisher Unwin. 15*s*.

The tubercular hip-joint which compelled young Shelford to spend many years lying on his back, and deprived him of the ordinary sports and pastimes of boyhood, developed in him a faculty of close observation of nature, which in later years, when health had been in considerable measure restored to him, he turned to good account. On leaving Cambridge, where he took both parts of the Natural Sciences Tripos, he spent two years as Demonstrator in Biology at the Yorkshire College, Leeds, and in 1897 he went to Borneo as Curator of the Sarawak Museum, established by Rajah Brooke at Kuching. Borneo is, of course, one of the happiest hunting grounds for the naturalist; and in the seven years which he spent there Shelford devoted himself enthusiastically to the study of tropical life. On returning to England in 1905 he was appointed Assistant Curator in the Hope Department of Zoology in the University Museum at Oxford; here he worked assiduously until 1909, when his former trouble broke out again, and led, after much suffering, to his early death in 1912. During his long illness he spent much time in preparing the notes which he had made of his work in Borneo. Unfortunately, the painful nature of his illness did not give him opportunity to complete the task, which was left in very considerable confusion; but the great skill and care with which Professor Poulton has edited these remains—although naturally they cannot hide the somewhat fragmentary nature of the volume—have given to us a work of original and remarkable interest.

Among the mammals of Borneo, no doubt the most interesting is the orang-utan, which is still plentiful in Sarawak, though very local in its distribution, being found only up the Simunjan, Balang Lupar, and Rejang Rivers. It is an extremely difficult creature to study, for it is essentially arboreal in its habits, and it moves rapidly along the higher branches of the trees, while the would-be observer can make little or no headway through the thick tropical undergrowth. The author contrived, however, to learn something of the orang's habits, both from wild specimens and from a young one which he kept as a pet for many months, and which he found "cleanly, affectionate, extremely intelligent and amusing." A remarkable photograph of an orang's "nest," or sleeping platform, is given. Little larger than a rook's nest, it is placed among the slender boughs near the top of a moderate-sized tree. The beast "lies flat on its back on its nest, and holds like grim death with hands and feet to the branches in the fork of which the nest lies; and so it passes the night, half supported by the frail platform, half suspended by the hands and feet, whose grip is secure even in the deepest slumber." It will be remembered that when the orang "Sally" escaped from her cage in the Zoological Gardens, Regent's Park, her first instinct was to make herself a "nest" in a neighbouring tree.

Two other interesting monkeys of Borneo are the pig-tailed macaque (*Macacus nemestrinus*), which is trained by the Malays to pick coconuts for its masters; and the crab-eating macaque (*Macacus cynomolgus*), which moves about in family groups, and is so co-operative in its habits that "in cases of difficult parturition the other females act as accoucheuses, with sometimes disastrous results to the baby." A couple of photographs taken by the author of the Bornean lemur (*Tarsius spectrum*) deserve notice, as the animal is very little known even among naturalists, no specimen having ever reached a European menagerie.

The birds, reptiles, and insects of Borneo, of course, provide wonderful material for the field naturalist, and Mr. Shelford's chapters on these subjects will be read with much interest. They are followed by a section on mimicry, of which the author takes a wise and moderate view, and by three or four miscellaneous chapters dealing with various anthropological questions.

GENERAL NOTES.

THE SUEZ CANAL.—According to a White Paper giving returns of the shipping and tonnage of the Suez Canal, the net tonnage for 1915 shows a decrease of 4,143,340 tons as compared with 1914, and a decrease of 4,767,729 tons as compared with that of 1913. The reduction of the transit dues to f.6.25 per ton from January 1st, 1913, together with the reduction of tonnage, had the effect of reducing the gross receipts, which amounted in 1915 to f.93,522,616, as compared with f.122,248,853 in 1914 and f.126,650,934 in 1913. The increase of 50 centimes per ton in the transit dues, which came into effect on April 1st, 1916, is expected to compensate partly for the reduction in the receipts caused by the decreased tonnage. The number of vessels which passed through the Canal was 5,085 in 1913, 4,802 in 1914, and 3,708 in 1915, of which 2,951 in 1913, 3,078 in 1914, and 2,736 in 1915 carried the British flag. There was a decrease of 1,254,240 tons in 1915 as compared with 1914 in the tonnage of British vessels, which amounted to 12,052,484 tons in 1913, 12,910,278 tons in 1914, and 11,656,038 tons in 1915. During the same period the tonnage of German vessels decreased from 3,352,287 tons in 1913 to 2,118,946 tons in 1914, and disappeared entirely in 1915. The percentage of British vessels and their net tonnage in 1915 was 73·8 and 76·3 respectively, against 64·1 and 66·5 in 1914 and 58 and 60·2 in 1913. The number of troops carried through the Canal in 1915 was 119,812 as against 228,720 in 1914, being a decrease of 108,908. There was an increase of 715 French, 143 Dutch, and 61 Belgian, against a decrease of 82,969 British, 14,782 Turkish, 6,075 German, 5,999 Italian, and 2 Spanish as compared with 1914. The number of civilian passengers was 86,653 in 1915 against 155,183 in the preceding year, being a decrease of 68,530; while the number of pilgrims, emigrants, and convicts was 4,065 in 1915 compared with 7,869 in 1914, or a decrease of 3,804. In the year 1870 only 26,758 civil and military passengers were carried through the Canal. The mean duration of passage for all vessels navigating the Canal during 1915 was 17 hours 58 minutes.

PURIFICATION OF WATER BY ULTRA-VIOLET RAYS.—River water is filtered, refrigerated and sterilised, then circulated through 12,000 ft. of 1-in. galvanised pipe to thirty-five sanitary drinking fountains in the plant of the Atlas Portland Cement Company at Hannibal, Missouri, by a supply system recently installed at an expense less than the old system of supplying the workmen with cooled water in barrels. The refrigerating plant consists of a 7½ in. by 7½ in. two-cylinder, vertical single-acting, enclosed, self-oiling, 12-ton York ammonia compressor, driven by a variable-speed 20 h.p. motor and a Shipley double-pipe, flooded condenser. The cooling tank contains 1,200 ft. of 1¼-in. pipe in expansion coils. Besides refrigerating the drinking water, the plant freezes 600 lb. of ice daily for use around the plant. The 12,000 ft. of pipe through which the water is circulated is broken up into loops through which the refrigerated water is pumped. The longest of these loops contains about 5,000 ft. of pipe. Most of the pipe is laid 3 ft. under the ground, with no other insulation than the clay, the piping above the ground being covered with a cork lagging. Fifteen hundred gallons of water are circulated per hour, leaving the pump at an average temperature of 40° F. and returning to the cooling tank at temperatures fluctuating between 50° F. and 55° F. Thus a fairly uniform temperature is obtained at the fountains, varying between 40° F. and 50° F. according to their location in the several loops. The sterilisation of the water is one of the unique features of the installation. The apparatus, known as a RUV steriliser, utilises the ultra-violet ray as produced by a special mercury-vapour lamp sending its rays into the water through a quartz tube. The new drinking-water system reduced the expense and trouble connected with supplying the workmen with water and ice in barrels, at the same time giving the employees the benefit of a drinking water that is both pure and cold.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

JANUARY 24.—W. A. M. GOODE, Hon. Secretary, National Committee for Relief in Belgium, "Relief Work in Belgium."

JANUARY 31.—MISS ELLA C. SYKES, "The Work of the Y.M.C.A. in France."

FEBRUARY 7.—ROBERT FORTESCUE FOX, M.D., "The Future of British Spas." SIR THOMAS BARLOW, Bt., K.C.V.O., F.R.C.P., M.D., LL.D., F.R.S., will preside.

FEBRUARY 14.—LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Byways."

FEBRUARY 21.—MRS. C. HOSTER, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment."

FEBRUARY 28.—FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

MARCH 7.—JAMES HARRIS VICKERY, LL.B., "German Business Methods."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

FEBRUARY 15.—PROFESSOR H. MAXWELL-LEFROY, M.A., F.E.S., F.Z.S., Imperial College

of Science and Technology, "The Indian Silk Industry." The RIGHT HON. LORD ISLINGTON, P.C., G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

MARCH 15.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

APRIL 19.—D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

MAY 17.—SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

JANUARY 30.—OCTAVIUS C. BEALE, Representative and Past President of the Australian Associated Chambers of Manufacture, "Imperial Industries after the War." The RIGHT HON. WALTER H. LONG, P.C., LL.D., F.R.S., M.P., Secretary of State for the Colonies, will preside.

FEBRUARY 27. — ALFRED BIGLAND, M.P., "Imperial Assets and how to use them."

MARCH 27.—The HON. FREDERICK W. YOUNG, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced :—

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

DR. M. HORN, "The Belgian Colonies."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

January 29, February 5, 12, 19.

HOWARD LECTURES.

Monday afternoons, at 5 p.m. :—

WILLIAM RIPPER, D.Eng., D.Sc., Professor of Engineering, University of Sheffield, "Works Organisation and Efficiency." Three Lectures.

April 23, 30, May 7.

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m. :—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 5, 12, 19.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, JANUARY 23...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Old Brain and the New Brain." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. F. J. Waring, "On the Physical Features of 'Adam's Bridge,' and the Currents across it, considered as affecting the Proposed Construction of a Railway connecting India with Ceylon."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Messrs. D. E. Benson, W. B. Ferguson, and F. F. Renwick, "A Simple Form of Accurate Density-Measuring Apparatus."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m. Mr. A. W. Gattie, "Goods Transport Reform at Home and Overseas."

WEDNESDAY, JANUARY 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. W. A. M. Goode, "Relief Work in Belgium."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. Mary Scharlieb, "The Prevention and Arrest of Venereal Disease in Women."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Rev. M. Summers, "A Great Mistress of Romance: Ann Radcliffe (1764-1823)."

THURSDAY, JANUARY 25...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir Walter Raleigh, "The Strength and Weakness of Romantic Poetry." (Lecture II.)

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. C. R. Peers, "The Care of Ancient Monuments."

FRIDAY, JANUARY 26...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. P. Norman, "Queen Square, Bloomsbury."

Royal Institution, Albemarle-street, W., 5.30 p.m. Professor G. Murray, "Epicurean Philosophy."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture II.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, JANUARY 27...Royal Institution, Albemarle-street, W., 3 p.m. Mr. A. R. Hinks, "The Lakes and Mountains of Central Africa." (Lecture II.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—January 19, 1917.

Journal of the Royal Society of Arts.

No. 3,349. VOL. LXV.

FRIDAY, JANUARY 26, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

MONDAY, JANUARY 29th, at 4.30 p.m. (Cantor Lecture.) PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." (Lecture I.)

TUESDAY, JANUARY 30th, at 4.30 p.m. (Colonial Section.) OCTAVIUS C. BEALE, Representative and Past President of the Australian Chambers of Manufacture, "Imperial Industries after the War." The RIGHT HON. WALTER H. LONG, P.C., LL.D., F.R.S., M.P., Secretary of State for the Colonies, will preside.

WEDNESDAY, JANUARY 31st, at 4.30 p.m. (Ordinary Meeting.) MISS ELLA C. SYKES, "The Work of the Y.M.C.A. in France." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

WEDNESDAY, JANUARY 24th, 1917; MR. A. SHIRLEY BENN, M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society :—

Beale, Lieut.-Colonel W., c/o Thomas Cook and Son, Ludgate-circus, E.C.

Blades, Alfred, Messrs. Blades, East and Blades, 23, Abchurch-lane, E.C.

Burnett-Hurst, Professor Alexander Robert, Sydenham College of Commerce and Economics, University of Bombay, Bombay, India.

Dreer, William F., 2121, Garden-street, Santa Barbara, California, U.S.A.

Hazard, Frederick Rowland, Syracuse, New York, U.S.A.

Islington, The Right Hon. Lord, P.C., G.C.M.G., D.S.O., 8, Chesterfield-gardens, W.

Krishna, Siri, M.A., Ludhiana Ice Factory, Ludhiana, Punjab, India.

Kumar, Hukm Chand, B.A., D.A.V. High School, Quetta, Baluchistan, India.

McCrone, Robert, Haughbank House, Mauchline, Ayrshire, N.B.

Mackenzie, Lady Owen, 6, Chesham-street, S.W.

Ong Boon Tat, 29, South Canal-road, Singapore, Straits Settlements.

Reid, Sir Marshall Frederick, C.I.E., Woodcote Lodge, Epsom, Surrey.

Ring, John, 508, Merchants' Exchange, St. Louis, Missouri, U.S.A.

Schuster, Professor Arthur, D.Sc., F.R.S., Yeldall, Twyford, Berks.

Sethi, Seth Mauckchand B. (Tazr-ul-Mulk), Gwalior, India.

Sheppard, William Didsbury, C.I.E., East India United Service Club, 16, St. James's-square, S.W.

Tabor, Frederick Richard, 3, Duke-street, Adelphi W.C.

Tilston, Henry Edward, M.I.N.A., Calle Cangallo 499, Buenos Aires, Argentina, South America.

Waterlow, Edgar L., Messrs. Waterlow and Sons, Ltd., Great Winchester-street, E.C.

Wigglesworth, Edwin, 9, Carlton Mansions, Holland Park-gardens, W.

THE CHAIRMAN, in introducing Mr. Goode, the reader of the paper, said that everyone recognised how difficult the work of relieving Belgium was, and how absolutely necessary it was that it should continue. It had been carried on in a very remarkable and thorough manner by the Neutral Commission, with whose work Mr. Goode, who was the Honorary Secretary of the National Committee for collecting funds in the British Empire for the relief of Belgium, was fully conversant.

The paper read was—

RELIEF WORK IN BELGIUM.

By W. A. M. Goode,

Hon. Secretary, National Committee for Relief in Belgium.

The work of saving life is so less dramatic than that of destroying it that the average public, quite naturally, knows little and apparently cares little as to why or how ten million Belgian and French citizens have been kept alive during the two years that Germany has occupied the territory they inhabit. The death in battle or by massacre—and the latter is a contingency perpetually to be guarded against—of 10 per cent. of these people would "stagger humanity" even in these times, and might be a crucial point in world history; but the outwardly prosaic task of protecting all of them and keeping them alive slips by comparatively unnoticed in the intimate tragedy of a war that brings a knock from death at the door of nearly every home. Yet this preservation of almost the whole of one nation, and of an appreciable part of another, constitutes an undertaking which, in scope and complexity, can only be compared to the war itself. And I may as well say at the outset that, knowing my own limitations, I despair of doing justice to the undertaking or to those who undertook it. I would also like to add that, until the war is over, there are phases of the affair—phases that present themselves to almost every thinking mind—that must be left unexplained or only partly cleared up, because our attitude toward the enemy and our relations with our Allies and neutral powers are constantly being involved by the conduct of this Belgian relief.

At the risk of boring those who have watched and loyally helped the work, I must first of all remind you how relief in Belgium came to be necessary, and how it was instituted. The invasion of Belgium began on August 4th, 1914, and by October 15th of the same year the Germans held practically the whole country, with seven and a half million Belgians as captives. The Germans, quoting the Hague Convention, which seems almost super-Biblical in the elasticity of its interpretation, declared that it was the duty of the occupied country to maintain the occupying army, and that if scarcity arose it must be attributed to the blockade of Belgian ports by the Allied navies. Conquest and requisition had destroyed supplies and paralysed industry, with the result that a country which in time of peace was compelled to import three-quarters of its food supply found itself threatened with famine.

The question, many times, and with excellent reason, is asked: "If we had not relieved Belgium, would not Germany have been, in the last resort, compelled to feed the people?" The best answer to that lies in what actually happened in Belgium in the early days of October, 1914. In Charleroi the Germans compelled the municipal authorities to provide the bread necessary for the occupying troops. In reply to the burgomaster's protest that this would leave at least ten thousand inhabitants without the basis on which to sustain life, the burgomaster was told that that was no concern of the conquerors — it was the fault of the Allies. Exactly the same demands, with the same results, occurred at Liége and other centres, while in Brussels, Antwerp, and similar thickly populated cities, destitution automatically increased with such leaps and bounds that the seriousness of the problem quickly became apparent. Every scrap of evidence I have been able to gather—and I personally took down the burgomaster of Charleroi's statement when he came in haste to England early in October to beg for food to save his people, besides seeing many other credible witnesses and having access to all the official documents—convinces me that the Germans would at that time have been guilty of the crime of deliberately allowing the people in Belgium to reach such a stage of starvation as to compel them to riot, and thus give pretext for wholesale massacre of unarmed civilians by armed troops, while those who survived would have been decimated by disease due to underfeeding. It may be said that this is hypothesis, and that the initial action of the German occupying army was only meant to overawe the population and bluff the Allies into eventual feeding of the people. My answer is, that in every known instance the Germans enforced their requisitions for food regardless as to whether or not their fulfilment involved immediate or threatened starvation; that they then and ever since have maintained that, in principle, the Allies were directly responsible through their blockade for any deaths that in consequence occurred; and that, subsequently, in Poland, while Polish potatoes were being sent to Switzerland, thousands of Poles actually starved to death because the Germans refused to feed them. There are some who say that what the Germans did in Poland is, in itself, convincing proof of what would actually have happened in Belgium; but I should prefer to put it more cautiously.

namely, that every act of Germany in accomplishing the conquest of Belgium definitely indicated that no mercy could be expected by the civilian population, and that our loyalty to an allied people—apart from any consideration of humanity, and apart from the lowest material reason of endeavouring to retain their allegiance while in captivity—inevitably dictated to us such a policy as was calculated to nullify Germany's preliminaries to starvation, and that we were not justified in regarding those preliminaries as a bluff. You cannot gamble with the lives of over seven million defenceless people when your only trump card is a belief that Germany will not descend to the depths of inhumanity.

This view was certainly shared by the United States Minister who remained in Brussels, by members of the American community, and by the Belgians themselves. An American-Belgian Committee had been formed in Brussels to alleviate the local destitution. As the magnitude of the problem dawned, and as the German attitude became more sharply defined, Mr. Millard Shaler, an American engineer, came to London, on behalf of the Brussels Committee, to secure the co-operation of his fellow-countrymen. There followed an urgent message from the American Minister in Brussels to Ambassador Page in London, asking for measures to be taken to avert famine, and also appeals from Charleroi and other centres.

These conditions led up to the formation of the Neutral Commission for Relief in Belgium. I make no excuse for taking up so much of your valuable time in recapitulating the preliminaries, because I feel sure that for years to come historical and military controversy will centre around the hypothesis as to what really would have happened if the seven and a half million Belgians in Belgium had been left entirely at the mercy of Germany.

As no great movement, justly or unjustly, can be dissociated from the personality of its leader, titular or otherwise, I am here compelled to speak of the man for whom the American Ambassador in London sent when he received the call for help. I say "compelled," because Mr. Herbert Hoover is aggressively averse to anything being said about himself when so much must be left unsaid about relief in Belgium. And yet, with the certainty of being rebuked, I record the opinion, quite impersonally and dispassionately, that without Mr. Hoover we should long ago have been unable to continue to relieve Belgium. Mr. Hoover is an eminent American engineer. On the outbreak of war he formed a committee in London to help the thousands of Americans who were suddenly stranded during their summer visit to our shores. So well did he do this that Ambassador Page, knowing also his world-wide experience in organisation and re-organisation, intuitively turned to him in October, 1914, and said: "Hoover, we've got most of our stranded Americans off; tell me what should we do about these appeals from Belgium?" If these were not the exact words, they, at any rate, represent the sense of an interview which has had incalculable effect.

The way I became connected with the work would be too ridiculously disproportionate for mention, except that it throws light on the character of the man responsible for it. The day after his interview with Ambassador Page, I went to see Mr. Hoover, by appointment, on a matter of ordinary business of some mutual importance. I waited an hour. Mr. Hoover came in, ordered a taxi, asked me to drive with him, and, totally ignoring what I had waited an hour to tell him, said: "I want you. We are trying to relieve Belgium." That same "I want you!" has brought to the aid of our Belgian Allies hundreds of Americans, who, with devoted self-sacrifice, have unostentatiously given their time, their money and their brains to the always difficult and often dangerous and sometimes thankless task of keeping alive a nation which our enemy threatened with extinction.

But I am anticipating. Mr. Hoover, with the co-operation of Ambassador Page, "overnight," so to speak, formed a committee of Americans in London and the United States to co-operate with their fellow-countrymen in Brussels. Diplomatic negotiations, with the strong support of President Wilson, were initiated for the recogn tion by the belligerents on both sides of a definite relief organisation, and meantime some immediate relief supplies were shipped. The Spanish Ambassador in London and the Spanish Minister in Brussels became, with their American diplomatic colleagues, patrons of the organisation, while at later dates the American Ambassadors in Berlin and Paris, the American Minister at the Hague, and the Netherlands Minister to Belgium also joined the Commission. A powerful committee was appointed in New York, and an appeal was issued by Mr. Hoover, with the approval of King Albert, to the American people, who responded with £1,000,000 within twelve months. A co-operating committee was

established in Brussels—the "Comité National" —a purely Belgian body, which included those leading bankers and business men who had remained, for mak ng arrangements as to the distribution of the relief.

That, in a very sketchy way, describes the genesis of the Neutral Commission for Relief in Belgium.

In March, 1915, at the request of French authorities, the Commission undertook to arrange for the feeding of the people in the occupied part of Northern France. At the end of April in 1915, the National Committee for Relief in Belgium, which I had the honour to organise, came into existence with the approval of His Majesty's Government. Its functions are to act as a central depository for all benevolent funds from the British Empire for the people in Belgium, and to issue appeals on their behalf. And while, with complete confidence, it remits all sums received to the Neutral Commission, it assumes no responsibility for the administration of those funds, except so far as it is authorised by His Majesty's Government, just as the Neutral Commission can have no responsibility for the necessarily un-neutral appeals and statements issued by the British National Committee.

To revert to the Neutral Commission. What in October, 1914, was an emergency committee, consisting of a few Americans in London and Brussels, acting as an ordinary charitable body, can now be described as one of the neutral powers in the war. Either directly or through its protecting ambassadors and ministers it has entered into extended and almost daily negotiations with the belligerent Governments, securing elaborate guarantees and arranging complicated agreements for none of which the world's diplomatic, political or military history provided precedent, any more than there was precedent for the existence of the Neutral Commission itself. There have been, I suspect, occasions when both belligerents, harassed into momentary irritation by internal and external crisis, would have liked to see the Commission for Relief in Belgium and its dogged chairman at the bottom of the sea; but these nerve-storms have almost invariably been succeeded by genuine admiration for the comprehensive grasp of the problem exhibited by Mr. Hoover and his colleagues, and for the "miracle of scientific organisation," to quote Lord Curzon, as presented by the self-sacrificing work of the Commission as a whole. I feel safe in adding that never during the war have the responsible heads of either the Allied or Enemy Governments ever for a moment doubted the strict neutrality of the Commission's acts. That, in itself, when tremendous issues hang upon the integrity and discretion of those who come and go with unequalled freedom between enemy countries, is a remarkable tribute. As to the devotion of the members of the Commission to the Belgian people, any outsider can draw his own conclusions regarding opinions likely to be held by American men of affairs who, without hope of reward and at great pecuniary sacrifice, gave up their occupations to serve as volunteers to save Belgium from the results of invasion.

To-day, thanks to the powers vested in it by the various belligerents, the Commission is practically responsible—with its co-operating organisation, the Belgian Comité National in Brussels and the Northern France Committee—for the entire feeding of about ten million people, of whom some 3½ millions in Belgium and 2 millions in France are totally destitute. Up to date it has expended on this work over £42,000,000. Of this amount some £5,000,000 has been contributed through the benevolence of the world, the balance representing subventions from the Belgian Government, supplied by the British and French Governments and by French institutions, with the notable addition of over £3,000,000, which is derived from profits made on the sale of food to those who could afford to pay for it. The Commission has already sent to Belgium and Northern France nearly three million tons of food, bought through its own voluntary branches in the world's primary markets and shipped by fifty or sixty cargo steamers, which week after week are employed to gather food from all quarters of the globe and to deliver it at Rotterdam. This unique merchant fleet sails under the Neutral Commission's own flag, is recognised by all the belligerents, and in itself would form the subject of a fascinating paper. Coincident with these amazing shipping and financial operations the American representatives of the Commission in Belgium, in conjunction with the Comité National and its 40,000 voluntary Belgian helpers, by an elaborate system which I will describe later, protect and personally supervise the distribution of all the food supplies until they reach those for whom they are intended.

This, I hope, has given a rough outline of how and why the relief work started, and what has been accomplished. As the problems connected with the Commission are complex, I ask your permission to deal with them under three

headings—viz., Political, Economic and Sociological, and Benevolent.

Political.

The one outstanding doubt, perpetually and rightly finding expression in public and private questions, is, "Does relief in Belgium help the enemy?"

Field-Marshal Lord French, in an interview published on the 3rd of this month, stated the best case I have seen as showing how the enemy benefits. Prefacing his remarks with the proviso that he spoke from the strictly *military* interests of the Allies, and was "leaving out of account all questions of humanity," our distinguished soldier declared that under the Hague Convention we had undoubted right to apply the blockade to Belgium after its occupation by Germany; that our decision to be humane had cost us over £22,000,000 in cash, besides seriously reducing the merchant tonnage so badly needed for our own food supplies; that the Germans had taken large amounts of home-grown live-stock and foodstuffs from Belgium, to say nothing of their seizures of raw material and machinery, or of their financial robbery by imposing on Belgium an indemnity that amounted to £100,000,000. Lord French concluded: "The indirect cost to the Allies has been that of relieving the Germans of all responsibility for the maintenance of over 7,000,000 people, whom, under international law, they were obliged to feed and maintain in health, and whom, moreover, they otherwise actually would have had either to feed or to deport wholesale, since it is impossible, from a military point of view, to have a starving population on the lines of communication of a great army."

All of which, to the casual reader, would give the impression that the sooner we stopped relieving Belgium the better for ourselves. Lord French, of course, committed himself to no such conclusion, and it seems to me a pity that his excellent summary of all the military advantages we have sacrificed in loyalty to our Belgian Allies and in the name of humanity was not accompanied by an expression of the opinion, which I believe he holds, that we adopted the only course consistent with our national honour, and that we should not swerve from it. The *Daily Telegraph*, commenting upon Lord French's statement, said, editorially:—

"Are these acts regretted by the British people? The question has only to be asked to answer itself, even though the enemy has thereby been strengthened economically at our expense and, at the same time, enabled to squeeze out of these miserable people forced contributions which must amount to not less than £100,000,000. The British policy towards Belgium, as towards neutrals, has been the very opposite of that adopted with merciless cruelty by the Germans. It is a mistake in war to take short views."

By a curious paradox, Count von Reventlow and other German military authorities have been publicly and privately agitating against allowing further relief supplies to go into Belgium. They maintain that but for the action of the Neutral Commission the civilian population in Belgium, or what was left of it, would by this time have succumbed to German pressure and German suasion, and that, to all intents, Belgium would have been a liege province of Germany. Basing, as Lord French also does, their arguments on purely military grounds, they declare that Belgian man-power could long ago have been starved into working except for the ration received from the Allies through the Commission, whereby they were enabled to maintain what will always be known as the greatest passive resistance in history. These German authorities insist that their Government have blundered, that the deportations of Belgian labour have come too late in the day to get good work out of men whose bodies and spirits have been so sustained that, despite two years of captivity, they could not be compelled to accept high wages, even at the point of the bayonet.

The historian of the war, with all the facts at his disposal, will probably find that both Lord French and Count von Reventlow had a good deal to justify their diametrically opposite views of the same military situation. Without entering into a further discussion on this point, and without touching upon the obvious and paramount question as to what would be the attitude of the Belgian Government if we left nine-tenths of the Belgian nation at the complete mercy of the Germans, I will read you the considered opinion of a distinguished member of the present Government, Mr. Walter Long, the Secretary of State for the Colonies, whose stalwart patriotism has never been questioned. Mr. Long wrote to the National Committee for Relief in Belgium, on the 2nd of this month, as follows:—

"It is obviously impossible to guarantee that no relief or advantage is derived by the enemy from the assistance given to those who suffer under their iron heel; but, on the other hand,

it is impossible to exaggerate the advantages which must accrue to the cause of the Allies by the work which is now being done for the relief of the unfortunate people who are bearing so courageously the bitter persecution of the Germans. There can be no doubt that this good work will bear fruit not only to-day, but in the future, when we come to the resettlement of boundaries and the relations between the different countries."

You will notice that, like Lord French, the Colonial Secretary excludes the humanitarian aspect; but, after taking into consideration the military view, he arrives at such a conclusion as may be expected of statesmanship. And in the opinion of the British National Committee the policy he enunciates, and the reasons he adduces for it, are incontrovertible. Speaking solely upon the humane phase of the problem, the same Minister expressed the opinion that if we now left the people in Belgium to subsist on what they could get from Germany, it would be the "blackest page in our national history."

It is essential to remember that the determination of our present Government to continue to relieve Belgium, and all the activities of the National Committee in furthering that policy, are only resultant upon searching investigations as to the precautions taken to safeguard the food supplies sent into Belgium. If it were not for the confident belief that every measure humanly possible was employed to prevent leakages to the enemy there might, in my opinion, be justification for the Government in reconsidering their policy of relief, with consequent cessation of our work as a national body. The nature of the precautionary measures employed I will deal with in a moment; but, in passing, I may say that those who have had these investigations in hand, and who have come into personal contact with Mr. Hoover, all share, not only a high appreciation of his transparent integrity, but a belief, based upon experience, that his pertinacity and fearlessness, backed up by the moral influence of the American and Spanish Governments, are a compelling force in making the Germans observe, at any rate to a degree scarcely to be expected, their guarantees. Otherwise he would not have been able to exact even such partial reparation as has been made in response to Allied protests against breaches in food agreements.

These agreements and their breaches are the cause of constant and trying negotiations between the Neutral Commission and the belligerent Powers. Two outstanding factors in connection with them should always be borne in mind. The first is that the leakages in food supplies cannot be *comparatively* appreciable, otherwise the people in Belgium would not be alive to-day, because only enough food has been allowed into Belgium through our blockade to provide a bare living ration. That ration, including the native supply, represents only 1,900 calories per capita per diem. The minimum considered necessary to maintain life and carry on light work is 2,400 calories. The average consumption per capita in the United Kingdom is about 4,000 assimilated calories. The second factor is that practically every one of the seven and a half million Belgians in Belgium is a spy, and rightly so, upon whatever the relentless invaders may do in connection with the relief supplies. Apart from the guarantees, and the American supervision, and the 40,000 educated Belgians engaged in distributing the food, every man, woman and child in Belgium is only too glad of the opportunity to tell of cases where food, which they know is intended for themselves, is taken by a German soldier.

The system enforced by the Neutral Commission for safeguarding the relief provided for Belgium by the Allied Governments and the benevolence of the world is, roughly, as follows:—

At Rotterdam, all food supplies consigned to the Commission are reloaded into canal boats or, in small proportion, into railway trucks. They are then sent under seal of the Commission to the terminal warehouses in Belgium, and thence reissued to 4,657 communal warehouses. The Rotterdam office charges each communal committee through provincial and regional committees with the amount of its consignment, and each commune has to pay, either in paper currency or in receipts from the destitute, for the amount of food received. It is obvious that the communes would not acknowledge their indebtedness unless they received their consignments in full, and the books of the Commission, which are audited in Brussels by representatives of the American house of Deloitte, Plender & Griffiths, show that there is no discrepancy as between the amounts shipped from Rotterdam and the amounts receipted for by the communes. From each communal warehouse the food supplies are issued direct to individuals under a card system, which I shall describe when I come to the economic and sociological section of this paper.

As a further precaution, the Commission have established at Brussels a bureau of statistics, whose sole business it is to verify the issues of

food from the communal warehouses with the returns which each commune is compelled to make of the rations they distribute to individuals. Not satisfied with this, the Commission maintain in every province another bureau of inspection and control, composed of Americans and Belgians, and over these bureaux there is a central control bureau in Brussels. Each of these bureaux has a force of inspectors whose constant occupation is to go from one commune to another to report upon the organisation and to investigate any complaints. As the final link in this chain of precautions, a staff of prosecutors is available to bring to justice any of those who may violate the guarantees or infringe the local regulations.

No system is perfect, and even with these minute safeguards the Germans break the spirit of the agreements; but the precautions taken fortunately assure that such breaches cannot do the enemy much good. When one also realises that before the Commission is allowed to take through our blockade a single ton of food the actual necessity for it has to be established to the satisfaction of our own Admiralty and war trade experts, there does not seem to be any loophole that has not been closed, so far as loopholes can be closed while an enemy holds captive ten million of our civilian Allies whom, in honour, we are bound to succour.

I should not be surprised if the principal political difficulty which the Neutral Commission have to face were their relations with the German authorities; but, as I am looking at Belgian relief through British eyes, I have intentionally confined this section of the paper solely to that phase which is all-important to the Allies.

Economic and Sociological.

The rationing of ten million people, not only in a state of industrial collapse, but ruled and isolated from the rest of the world by a hostile race, has naturally been an experiment replete with lessons invaluable to the economist and fascinating to the sociologist. Indeed, I am almost inclined to think, especially in view of our own immediate food problems, that it might have been wiser had I devoted the whole of this paper to the experiences and conclusions of those who planned and are now carrying out this unprecedented adventure in food distribution and control. I am permitted to quote a few excerpts from an invaluable memorandum drawn up by one who has fought out on the spot all those difficulties which, late in the day, we are now tackling for ourselves.

"The objective of any food control," he writes, "must be simply the tempering of consumption to necessity of supply, and its just distribution over the whole population." Dealing with the *repression* of food consumption by enforcing the maximum quantities that the consumer may purchase by the issue of household cards, he comments as follows:—

"It is worth bearing in mind that the success of the Belgian relief and the failure of the German system have been due to the intense decentralisation of the Belgian relief and the intense centralisation of the Germans. Decentralisation is the absolute keystone of executive success in any stage of individual rationing enforcement.

"In Belgium the relief has a central organisation which imposes general regulations and delegates the entire execution to 'provincial' volunteer committees. These committees again legislate for the provinces in expansion of the central regulations to local needs (as each province varies in character of population—urban, industrial, agricultural). In this connection it has been found advisable to set up the larger cities as 'provinces.' The 'provincial' committees in turn delegate execution to local volunteer committees, who dominate populations of from 1,000 to 5,000 people. In some large provinces a series of 'regional' committees are injected between the 'provincial' and 'local' committees. The 'local' committees (as others) are made up of principal residents, embracing men of commercial experience and usually employing a small paid staff. These 'local' committees issue the household cards and employ inspectors for their enforcement, and attend to other control functions as they develop in necessity. A certain number of regular inspectors attached to the provincial committees must be imposed over the local committees.

"Such a structure thus furnishes an administrative foundation upon which much wider functions can be imposed than merely the household-card issue. In the United Kingdom the local authorities might be blended into such a system as the above, provided the units of population are not too large—as is the case in some parishes."

As to the repression by distribution of a ration through establishing Governmental stores and kitchens, which is the Belgian relief plan, my authority says:—

"In this case the whole of the controlled commodities are aggregated into central stores, redistributed into regional stores, from thence

to local district stores, and the actual ration issued from these newly created agencies. This plan also involves the establishment of public kitchens for making soup and stew with a view to obtain an effectual distribution of meat. By this means the whole of the normal commerce in the commodities thus controlled is obliterated. The plan, while a necessity to Belgium and Northern France, is totally infeasible in any country where it is necessary or desirable to maintain economic life. It is a plan only desirable of introduction in the last stage of national starvation.

"The price regulation is one of extreme difficulty. For commodities which are wholly imported from abroad, such as sugar, there is no great difficulty in fixing prices all along the reticulation line; also for commodities which are predominantly imported, such as cereals, it is possible for the State to fix the price and the remuneration to millers, brokers, and dealers. Moreover, where native commodities are controlled by the committee system, it is possible, in a great measure, to fix prices. Where supplies, however, fall below the demand, and where there is no control of the commodity distribution from the source, any attempts to fix prices have usually proved an entire failure. The whole experience in Belgium and Germany in such cases has been the extraordinary disappearance of a given commodity from the public markets w thin a short time after fixing the maximum price. The explanation appears to be that such maximum price is only necessary where there is an under-supply, and that with an under-supply the well-to-do members of the community gradually set up direct relations with producers and aggregate to themselves, not only their normal supply, but accumulate supplies as against the future, and these transactions take place outside the maximum price. This latter, however, would not apply if the country were closely decentralised and the local committees were sufficiently energetic in controlling the distribution of excess production of any given district to another, for by the control of licences to dealers to transfer from one district to another prices can be stipulated."

I am also indebted to Mr. Robinson Smith, an able American, who ungrudgingly served for fourteen months in Belgium as a delegate of the Commission, for a remarkably vivid illustration of the system at work. Perhaps I ought to preface my quotation, although it will be apparent to you as I read on, by the statement that Mr. Robinson Smith has strong leanings towards State Socialism. Describing the supply of bread to La Louvière, in the Province of Hainaut, Mr. Robinson Smith gives this comprehensive picture, to which I respectfully draw Lord Devonport's attention:—

"With our communism then, that is with the monopoly of the necessities of life which the Commission enjoyed in Belgium during the war, the hundred kilos of wheat are not bought in the open pit in Chicago in competition, but are bought by an official of the Produce Exchange on that day on which few orders are in, and when therefore he knows the price will drop. The hundred kilos of wheat are conveyed to New York at a special price; are loaded on a steamer by a shipping company which gives its agency services free; are conveyed across the Atlantic at cheaper than the prevailing rates, because the Commission, that is the State, is able to employ a fleet of its own; are paid for in lower than the average bankers' rates, because the London office of the Commission has ever an eye as to where exchange can be bought lowest, and so in one year saved 509,650 dollars (which is slightly more than its entire overhead expenses); are discharged at Rotterdam by a floating elevator (rented from the city of Antwerp) at a lower price and in a shorter time than had ever prevailed in the port of Rotterdam, because the Rotterdam office, under a Mr. Young, aged twenty-seven, and a Dutchman, Van der Sluis, of the same age, are filled with this spirit of service and ambition to excel; are loaded into a 300-ton barge and conveyed to La Louvière at a cheaper rate than from Antwerp to La Louvière, although the distance is twice as great, because the State has a fleet of barges under its own control, and can regulate to a nicety their continuous employ with no losses by the way; are paid for by the provincial committee of Hainaut cash at the Brussels office before the barge leaves Rotterdam; are ground in the mill at La Louvière at a minimum price, because the miller is assured of continuous work with no bad credit, free from the worry of competition, except in so far as he knows that he would lose the job if he did not produce a good flour; are turned over as flour to a baker of La Louvière who, having no other flour on his premises, which must be cleanly. must turn over to the town of La Louvière at its bread depot on the following morn one hundred and thirty-five kilos of bread, the most that a hundred kilos of flour will conveniently produce, having had no chance to sift his flour since he must turn all of it into bread, no chance to adulterate his flour since his premises are

open to inspection and his bread is subject to analysis, and, what is more important still, such a system of distribution of the bread established that he would automatically lose his trade, a danger to which he would not be exposed to the same extent at least in ordinary commerce, since many clients are tied to their tradesmen by habit, by credit, or by proximity of the shop; and a poor article is slow in turning them from him. He is paid by the commune 8 francs a hundred kilos for making the bread, about half of which is profit, and since even a small baker usually bakes several sacks a day, and since he also has a small trade in other things and is preserved from bad credit, he is contented with the new order of things, finds nothing to complain of in Socialism, although we have always been told that communal ownership would destroy the individual. The only bakers who objected in the Hainaut were the Socialist co-operative baking societies, who were afraid that the hold which they exercised upon the working population by their extensive credit and dangerous methods of premium and annuities would be taken from them. They were also afraid that they should be obliged to produce better bread, and they were.

"La Louvière, in some ways, was the last word in the system, since one bread depot there served twenty-five thousand people, the whole town, nor were there said to be ever more than ten people in the depot at one time. The test of any distributing food, clothing or money centre is the absence of a line of people in front of it; whenever one sees a line of people standing in the rain or sunshine, one may be sure that there is a defect somewhere in the scheme of relief.

"La Louvière was divided into six districts of four thousand persons or one thousand families each. The town record showed how many persons slept under each roof, and each roof received a corresponding ticket for bread. The figure was confirmed by the responsible head of the house, and on his door a short notice said that the provincial committee of Hainaut was feeding so many persons in this house. Thus there was no chance that, auntie having been there the month before, someone should still receive her bread for her. Not that the neighbours did report such abuses, but the head of the house knew that they would if he was guilty. You do not care for such inquisitorial methods. But neither do you care for riots and revolution, and the provincial committee had to choose between the two, and could only be sure that it was doing its duty if it availed itself of every possible chance of saving and protected itself against every possible chance of fraud. Its ideal was not at all that of disturbing as little as possible the habits of the people, trying to make them forget that it was war. On the contrary, it continually overrode the habits of the people rough-shod, and the people did not murmur, with the result that they had always plenty of bread to eat and no cake; whereas Vienna, for instance, where the other ideal prevailed, had two hundred and ten grammes of bread per person per day (instead of three hundred and thirty-five), and anyone that could pay for it had as much cake as he pleased.

"Section one at La Louvière, rich and poor alike, one from each family, called with the family bread card at the central bread depot on Mondays and Thursdays (morning), between nine and ten if their name began with A, B, C, etc.; ten and eleven, if F, G, H.; section two on Mondays and Thursdays (afternoon), and so on. They thus received their bread twice a week, which was often enough except in the summer time. The usual rule in the province was three times a week. The person, whether man, woman, child or servant, presented his bread card, which indicated not only the number of persons in the family, but by a rubber stamp of a certain colour indicated the number of loaves that he was to receive on that day. There was no checking off to be done on the depot book, but the card was to be punched on the day of distribution, the thirteenth, for instance, which was the same ideally all over the province. The card had ninety of these numbers printed upon it, and was good therefore for ninety days of distribution or forty-five weeks here at La Louvière. The very expensive method of delivering new slips every day at the house or hotel or of bread cards which were good only for two weeks, the method that prevailed in Germany and Austria, was thus avoided, and there was much less chance of abuse. The rules and regulations both for the commune, the baker and the inhabitant were printed on the bread card, and thus everyone knew what he had a right to expect. These rules and regulations said that the person, upon arriving at the bread depot, had the right to take the bread from the rack of the baker whom he chose. Every baker at La Louvière had a rack in this bread depot, and delivered a quantity of bread equal at first to the quantity consumed by his original clientèle, but which, in the first weeks, varied according as from a comparison of

the appearance of the bread upon the racks or from a knowledge of the quality of the different breads when eaten, people, uninfluenced now by questions of propinquity or credit, freely chose the best bread. These quantities to be delivered by the baker soon became constant because automatically every baker baked as well as he knew how when he saw the danger to which poor bread was subject. Here one sees that this kind of Socialism employed competition, and competition unhampered by the usual hindrances that it meets with in trade."

The system, so interestingly illustrated by Mr. Robinson Smith, applies, with necessary variation, to the handling of bacon, lard, rice, soap, and so forth.

If Mr. Hoover were asked what his views were as to Belgian relief being a contribution to State Socialism, he would certainly say "Nothing whatever," on the grounds that, while one may command without payment or hope of reward the skill of the world over a period of emotion and devotion—such as the 40,000 volunteers from the Belgian intellectual classes connected with the relief organisation—neither these volunteers nor this devotion are possible as a constant human instrument.

Benevolence.

In accepting the invitation to read a paper before this Royal Society I thought I could best show appreciation of the compliment by confining myself mainly to the international and economic phases of Belgian relief, rather than by an endeavour to press home the appeal to charity which was inaugurated by His Majesty the King, and recently has been eloquently voiced by the Lord Mayor of London and by the religious and political leaders of our nation.

I will therefore endeavour to dismiss this part of the paper quite briefly. The benevolent account of the Neutral Commission shows an expenditure in Belgium up to October 31st, 1916, of over £26,000,000. This has been rendered necessary by the inability of over 3,500,000 of the 7,500,000 people in Belgium to pay for supplies. Towards this amount the public of the world had subscribed, up to the same date, only £4,940,038, and of this nearly £3,000,000 had been contributed from the British Empire. I may, perhaps, be pardoned for saying here that in twenty months the National Committee for Relief in Belgium have obtained solely from British sources over £2,150,000, or an average of £107,000 per month. The remainder comes mostly from generous sympathisers in the United States.

The ever-rising cost of food and shipping, combined with the alarming increase in destitution, render it difficult, if not impossible, for the Neutral Commission, even with larger Government subventions and with their wonderfully contrived profits, to make both ends meet. The increase in destitution is due in no little degree to Germany's refusal to permit the resumption of manufactures in Belgium, except on terms to which it would be suicidal for the Allies to agree, and to her inhuman deportations of partially or wholly employed men, thus throwing more women and children on the bread line. In reference to the Commission's "profits," I should like to explain that while these were made on commodities sold to those who could still afford to pay, the selling prices in Belgium were lower than those in London. This triumph of management could not have been achieved without effective service, freely given, on both sides of the Atlantic. For instance, two of the largest English firms manage the Commission's fifty or sixty vessels free of all charge—the equivalent of a gift to date of at least £200,000—while in the United States, the Argentine, and Holland, the Commission receive concessions in purchase prices, besides free or reduced railway facilities, harbour dues, wharfage, and agents' services. The £3,000,000 "profits" also represents, to some small extent, the value of the services of those American business men who, here in London, in the United States, and in Belgium, have gladly given practically their whole time to making the work of the Commission efficient. I suppose it is scarcely necessary for me to say that these "profits" are automatically applied to alleviating the distress in Belgium.

To revert to the present needs of the Neutral Commission. If they are to feed the people in Belgium, as the medical authorities say they should be fed in order to enable them to resist disease, an estimated monthly deficit of over £700,000 has to be faced, despite the monthly subsidy of £1,500,000 which is provided in equal parts by the French and British Governments. This deficit must be met by the benevolence of the world, and such profit as can be obtained; but in these days of increase in prices and decrease of the well-to-do in Belgium, profit must obviously be precarious. To help meet this deficit, and especially to relieve the suffering of the children and to check the alarming increase of phthisis among the

adolescents, the National Committee for Relief in Belgium are unceasingly asking for more donations from the British Empire. It is frequently suggested to me that the British Government should lend Belgium, or the Neutral Commission, out of increased taxation the whole amount necessary to keep her people in an adequate state of health. An inquiry of this character came less than a month ago from the Governor-General of Australia, and Mr. Walter Long, the Secretary of State for the Colonies, authorised us to reply as follows:—

"It is impossible to exaggerate the value of the knowledge that a portion of the funds comes from the free subscriptions of people in distant parts of the British Empire. If the money came only from the coffers of the State, there would not be the same sentiment of gratitude and affection which is widely created by the knowledge that citizens of the British Empire in its most distant parts are freely giving for the relief of suffering Belgium to-day."

I can conceive no two sentences that could more effectually answer the inquiry. And it is just as well to bear in mind that, prior to the formation of our own National Committee, the Germans were industriously circulating in Belgium and neutral countries the libel that although Belgium sacrificed herself for us, we were callously allowing her wounds to be bound up by America. The slander was quickly scotched by the magnificent response of the British Empire to our appeal. But if we now expressed our solicitude for Belgium solely in terms of a Government grant, we could hardly expect the public in the United States and other neutral countries to continue those individual donations, each one of which, however small, must bring home to the giver the realisation of the misery brought upon the world by Germany's violation of Belgian neutrality.

This suggests propaganda, and reminds me that I have been asked to say that in the course of its twenty months of existence the National Committee for Relief in Belgium have distributed over twenty-seven million publications, ranging from sixteen-page illustrated pamphlets to one-page leaflets enclosed in a Christmas dinner-table envelope, and including such striking indictments of Germany as Raemaecker's famous poster depicting the Belgian woman with a terror-stricken child at her breast. The important point of this distribution is that, with the exception of a very few hundred thousand, all these millions of copies have been actually *applied for* by branch committees or by individuals, thus assuring a maximum of effect and a minimum of wastage. The figures I have mentioned do not, of course, include countless articles exposing the infamy of Germany, which have been published in thousands of newspapers throughout the world. It may also interest you to know that the expenses, which are *not* deducted from the donations, incurred in raising over £2,150,000, and which include the cost of the propaganda I have just described, do not exceed one per cent.; that the children in our elementary schools, both in the United Kingdom and the Empire Overseas, give, in proportion to their means, far more generously than the adult; that the poorer classes are undoubtedly the best givers, probably because the Belgian cry of hunger and privation comes nearer home; that over £1,450,000 of the £2,150,000 was contributed by Australia and New Zealand; that the War Charities Act was passed as the direct result of repeated representations made by the National Committee for Relief in Belgium, and that we have never spent a penny on an advertisement in a daily newspaper, although we, and Belgium, owe to the press of the British Empire a debt of gratitude that can never be measured in money.

I mention these things because they may be of value to those who are so devotedly co-operating here and throughout the Empire in our work, and because they have relative usefulness to those connected with other war-relief efforts. But they sink into paltry insignificance if one dwells for a moment upon the mental anguish and the physical suffering of the seven and a half million people under German domination in Belgium. For two long years and three months they have awaited deliverance with a fortitude that compels admiration even from the enemy. During all this time most of them have patiently subsisted upon a ration only fit for a beleaguered garrison. Many of the women were widowed in the first atrocious days of invasion, while thousands of others have quite recently lost their husbands and sons—slave-raided into Germany, because they dared and still dare to refuse to work for the conqueror. And, as the months of their third winter of captivity drag on, there is tragic increase in the number of mothers who see their growing boys and girls, for want of proper nourishment, droop and die under the scourge of consumption. It is for these children and their mothers that the National Committee for Relief in Belgium confidently ask the compassion and the loyal aid of the British Empire.

DISCUSSION.

Mr. E. H. Rhodes (Local Government Board), after mentioning that Lord Rhondda would have been present had it been possible, said he would like to deal with the paper from the point of view of the Local Government Board. It was not the province of that Board to have any extensive relations with the National Committee for Relief in Belgium, their work being in connection with the Belgian refugees in this country. The Local Government Board was the Government Department that provided the framework within which the War Refugees Committee had done such excellent work. He had been astonished, as everyone else must have been who had read the early reports of the National Commission, at the number of ships engaged in the work, and at the amount of cargo that was carried into Belgium; and he was still more struck by the loving care in matters of detail which the later reports showed had been displayed, as, for instance, in the care of children and in the providing of special food for them. That loving care in matters of detail was as remarkable as the immense scope of the work that was carried on. Within the last day or two it had occurred to him whether those who were concerned with the Belgians in England could not make more use than they had done of the Spanish-American Commission. There was a large number of Belgian workmen working in this country, many of whom were obliged to leave their wives and families in Holland or Belgium, and the Local Government Board thought it would add greatly to the comfort and contentment of those men if their wives and families could be brought over to join them in this country. That was not a matter of great difficulty with regard to those that were in Holland, but with regard to those in Belgium the efforts of the Local Government Board had resulted in a complete failure. He had got out some statistics a month or two ago, and found that of the 700 people in Belgium to whom letters had been addressed only about fifteen had succeeded in reaching this country, and even in regard to those fifteen he was not quite sure whether their success was not due to some act of dare-devilry or some piece of luck on their own part rather than to the skill of the Local Government Board. He thought in that connection more use might be made of the Spanish-American Commission, for he understood that that Commission was directly in touch with the people; but he supposed an objection to that would be that, as the Commission was a Neutral one, it could not help in a work carried out through a British Government office.

The Right Hon. Sir Joseph Ward, Bt., K.C.M.G., said that, as a representative of New Zealand, he had listened to the paper with great interest, and he thought that the effect of its publication—or the publication of extracts from it—in the press of that country would remove some of the misconceptions that had been circulated with a view to stopping the people there from continuing to assist the Belgians in their dire distress. It was not so very long ago that it had been represented to him, in his official position, that all the contributions the people of New Zealand were giving were really undeserved, and that the refugees in this country were proving themselves to be unacceptable to the British people. But in New Zealand they refused to concern themselves with the attitude of any of the refugees, or with the opinions that were being formed regarding them in any country outside of Belgium. They remembered the fact that at the beginning of the war they, as a section of the British community, had been saved by Belgium from the terrible disaster that might have over taken the British Empire, and, however much information might be viciously circulated with the object of interfering with the charitable disposition of the people of New Zealand, they went back to those first principles which had been their guide in connection with the relief of Belgium. In connection with the author's remarks about the communal system not working satisfactorily, he advised him to go out to New Zealand and live among the Maoris to obtain a contradiction of his opinion. The Maoris lived under a communal system; the majority of them were well-to-do; there was hardly one of them who had been known to go into a household to do menial work for a European; and they had splendid estates and a great deal of money. He had believed all along that a portion of the contributions sent into Belgium was being utilised for the assistance of the enemy; but surely the noble sentiments expressed by the author clearly demonstrated that it was our duty to help in the work of relief, even if we had a barbarous enemy who was prepared to rob the Belgians of their food supplies. The people of New Zealand had already spent some £2,000,000 in providing comforts for their soldiers, besides doing many other things for the support of the men who were fighting for their King and country; in addition to that they had sent £764,000 to this country to help the Belgians and Serbians, and also to help those who had been left by the noble men who fought at the battle of Jutland, and the Government of New Zealand was now giving £10,000 a month to the National Committee in London. They were going to continue that work until the end of the war, and he thought the author's paper would stimulate them in their efforts.

Sir Robert W. Perks, Bt., earnestly hoped that the time would never come when bread tickets and rations would be needed in this country, and, thanks to our Navy and Army, he did not think such things would ever have to be seriously contemplated. One of the most charming features of the flow of benevolence that had gone on in connection with the Belgian and other relief funds was the total

absence of any other consideration in the minds of the donors than the needs of the people. He had received a very considerable amount of money from Canada for distribution amongst the people of this country and our Allies, and, although that money came from people who had rather narrow ways of thinking in some respects, he had been instructed to take into consideration only the need of the people, without regard to their religious opinions or any other matters. He congratulated the author on his paper and also upon the ability which had enabled him to write it. The people of this country were proud that they could always find men to do its work efficiently on land or sea, and he believed that whatever difficulties might confront the country in days to come they would be able to grapple with them as their forefathers had done.

MR. ALDERMAN D. A. GRIFFIN referred to the enormous amount of wealth in jewellery and clothes, etc., contained in this country, and could not imagine how anyone could keep large quantities of such things when there were starving children in Belgium within a few hundred miles of them. In that connection he had made an experiment in Ealing on behalf of the Polish Relief Fund, and appealed in the local press for jewellery and other things of a similar nature. The result was that he got six replies, all being from poor people, which bore out the author's statement that the poor, according to their means, had come forward better than the people who had more of this world's goods.

HIS EXCELLENCY THE BELGIAN MINISTER, speaking in French, expressed the gratitude of his country for the work which had been carried out by the National Committee for Relief in Belgium—a most valuable work of social service and charity. In thanking those who had contributed to the cause, he desired to place on record his appreciation of the part played by New Zealand, to which Sir Joseph Ward had referred. He would like also to thank Mr. Goode for his admirable paper, and for the whole-hearted manner in which he had devoted himself to the task of Belgian Relief.

On the motion of the CHAIRMAN (Mr. A. Shirley Benn, M.P.), a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

OBITUARY.

SIR WILLIAM ERSKINE WARD, K.C.S.I.—The death of Sir William Erskine Ward took place at his residence in Ealing on December 24th. He was born in 1838, the son of the Hon. J. P. Ward, and nephew of the third Viscount Bangor. He was educated at Trinity College, Cambridge, and, after graduating as a Senior Optime, he entered the Bengal Civil Service in 1861. In 1876 he was transferred to Assam, and served as Judge and Commissioner of Assam Valley districts. From 1889 to 1891 he was Judicial Commissioner of Lower Burma, and for the next five years Chief Commissioner of Assam. He retired in 1896, when he was created K.C.S.I. in recognition of his services.

Sir William became a member of the Royal Society of Arts in 1900. He was interested especially in the meetings of the Indian Section, and in 1903 contributed to the *Journal* a long and valuable note in connection with Sir Charles Lyall's paper on "The Province of Assam."

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

JANUARY 31.—MISS ELLA C. SYKES, "The Work of the Y.M.C.A. in France." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

FEBRUARY 7.—ROBERT FORTESCUE FOX, M.D., "The Future of British Spas." SIR THOMAS BARLOW, Bt., K.C.V.O., F.R.C.P., M.D., LL.D., F.R.S., will preside.

FEBRUARY 14.—LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Byways." The RIGHT HON. LORD FARRER will preside.

FEBRUARY 21.—MRS. C. HOSTER, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment."

FEBRUARY 28.—FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

MARCH 7.—JAMES HARRIS VICKERY, LL.B., "German Business Methods."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

FEBRUARY 15.—PROFESSOR H. MAXWELL-LEFROY, M.A., F.E.S., F.Z.S., Imperial College of Science and Technology, "The Indian Silk Industry." The RIGHT HON. LORD ISLINGTON, P.C., G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

MARCH 15.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

APRIL 19.—D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

MAY 17.—SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

January 30.—Octavius C. Beale, Representative and Past President of the Australian Associated Chambers of Manufacture, "Imperial Industries after the War." The Right Hon. Walter H. Long, P.C., LL.D., F.R.S., M.P., Secretary of State for the Colonies, will preside.

February 27. — Alfred Bigland, M.P., "Imperial Assets and how to use them."

March 27.—The Hon. Frederick W. Young, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

May 1.—Philippe Millet, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced :—

Sir C. Arthur Pearson, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

Joseph Pennell, "The Artistic Aspects of War Work."

Gabriel Gordon Cleather, "The Drum."

Horace M. Thornton, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

Dr. M. Horn, "The Belgian Colonies."

Dr. J. Augustus Voelcker, "Fertilisers and their Supply in War Time."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. :—

Professor A. Beresford Pite, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

Syllabus.

Lecture I.—January 29.—*The Ancient World.* Civilisation—Method and art in city building—Egypt, Nineveh, Babylon, Athens, and Rome—Greek and Roman colonies.

Lecture II.—February 5.—*Mediæval and Renaissance Periods.* Republics and Duchy towns of Italy—Florence, Venice, Milan, Rome. Free cities of the Empire—Nuremberg, Ghent, Ypres, Bruges, Antwerp, and Brussels. France and Germany. English types.

Lecture III.—February 12.—*The Nineteenth Century.* Paris under the Empire. Vienna—Ringstrasse and buildings. Berlin—Centre and growth. Washington, New York, and Chicago. England—Late Georgian and Victorian progress.

Lecture IV.—February 19.—*The Housing and Town Planning Act*, 1909. Problems for solution. Procedure. Advice to promoters. Preparation of schemes. Architectural considerations. Examples of Garden City movements—Letchworth, Hampstead, etc. The problem of London.

MEETINGS FOR THE ENSUING WEEK.

Monday, January 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor A. Beresford Pite, "The History and Practice of Town Planning and Civic Architecture." (Lecture I.)

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Mr. H. Withers, "Problems of Taxation."

Tuesday, January 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. O. C. Beale, "Imperial Industries after the War."

Asiatic Society, 22, Albemarle-street, W., 4 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Old Brain and the New Brain, and their Meaning." (Lecture III.)

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. G. Avenell, "Richard Jefferies."

Wednesday, January 31...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Miss Ella C. Sykes, "The Work of the Y.M.C.A. in France."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 4.30 p.m. Dr. W. L. Mackenzie, "The Physical Welfare of Children after Infancy from the National, Social, and Public Health Standpoints."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. C. J. Macalister, "The Prevention and Arrest of Venereal Disease in Men."

Thursday, February 1...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. A. F. Joseph and W. N. Rae, "Chromium phosphate." 2. Mr. K. C. Browning, "The detection of traces of mercury salts in toxicological work." 3. Mr. R. V. Wheeler, "'Stepped' Ignition." 4. Mr. H. Rai, "The catalyptic bleaching of oils, fats, and waxes." 5. Mr. P. C. Ray, "Alkaloidal derivatives of mercuric nitrite." 6. Messrs. P. C. Ray and M. L. Dey, "Synthesis of a derivative of the lowermost homologue of thiophene." 7. Mr. S. U. Pickering, "The detergent action of soap." 8. Messrs. E. H. Archibald and H. B. Keegan, "The occlusion of iron by the phospho-molybdate precipitate."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. G. Donnan, "The Mechanism o Chemical Change." (Lecture I.)

Friday, February 2...Royal Institution, Albemarle-street, W., 5.30 p.m. Dr. C. Carpenter, "The Supply f Gaseous Energy."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture III.)

Saturday, February 3...Royal Institution, Albemarle-street, W., 3 p.m. Dr. H. W. Davies, "Line in Plain Chant and Folk Song." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,350. VOL. LXV.

FRIDAY, FEBRUARY 2, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 5th, at 4.30 p.m. (Cantor Lecture.) PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." (Lecture II.)

WEDNESDAY, FEBRUARY 7th, at 4.30 p.m. (Ordinary Meeting.) ROBERT FORTESCUE FOX, M.D., "The Future of British Spas." SIR THOMAS BARLOW, Bt., K.C.V.O., M.D., LL.D., F.R.C.P., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, January 29th, PROFESSOR A. BERESFORD PITE, F.R.I.B.A., delivered the first lecture of his course on "Town Planning and Civic Architecture."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, January 30th; The RIGHT HON. SIR JOSEPH G. WARD, P.C., K.C.M.G., LL.D., in the chair. A paper on "Imperial Industries after the War" was read by Mr. OCTAVIUS C. BEALE, Representative and Past President of the Australian Associated Chambers of Manufacture.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, January 18th, 1917; The RIGHT HON. VISCOUNT BRYCE, O.M., D.C.L., LL.D., F.R.S., in the chair.

The paper read was—

BETWEEN THE TIGRIS AND THE INDUS. THE BEN-I-ISRAEL.

By COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.

On our Indian frontier, some two hundred miles to the west of Peshawur, there is an upland of open rolling plains, intersected and encompassed by rugged mountains, well watered and fertile, enjoying, on the whole, a temperate climate, bright and warm with sunshine in summer and wrapt in the snowy mantle of an Eastern Switzerland in winter. It is, indeed, a Land of Promise. I know nothing more beautiful than the promise of late spring in this land. Then the wide plains are spread with a shimmering sea of upspringing corn, and at the far edges of the plains the lower slopes of the mountains are half-veiled in a light-blue haze which faintly reveals white villages clinging to their craggy spurs. Near by, the running streams of bronze irrigation water, bordered by groves of mulberry and scented willow, are often pink with the scattered petals of peach and almond blossom. It is a land of the vine and the olive and the melon, and of a great wealth of later autumn fruits. In winter it is icebound, with much display of the fantastic beauty of ice shapes in waterfall and river fashioned by the frost grip under the shadow of the snow-capped hills which stand round about its outspread capital; but the winter is the winter of Switzerland. This is the home of the Ben-i-Israel. The capital town, crescent-shaped and hill-protected, is Kabul; and the country about it is the upper Kabul River basin, a part (and perhaps the most important part) of Afghanistan. The name Afghanistan arouses many memories in many of us; one unfailing point of interest in connection with it is its origin. Afghanistan means, of course, no more than the home of the Afghan; but who is the Afghan, and where does he come

from? The name has become crystallised now in Indian history and Indian frontier records for nearly two centuries, but it is apparently only as old as the days of the founder of the Durani dynasty, Ahmad Shah, and it is not a name, so far as I know, acknowledged by any one of the extraordinarily mixed nationalities that occupy Afghanistan. There are Turks and Tajiks, Arabs, Persians and Monguls, with Pathans of mixed origin and all of very ancient lineage, and there are the Ben-i-Israel—but no specific Afghan. I know no one from the mountains of Kafiristan to the deserts of Baluchistan who calls himself Afghan. It is, however, just as well that we should have a recognised British official term for all the peoples governed from the Kabul centre of administration within the boundaries fixed to the Amir's dominions, and the name Afghan is far too useful to quarrel with.

The Ben-i-Israel belong to (if they do not comprise) those Durani clans who established themselves as the dominant power in Afghanistan after the death of the great Persian ruler and robber, Nadir Shah, in the eighteenth century, and, consequently, the Amir of Afghanistan is their ruler and chief. They spread over a great part of the upper basin of the Kabul River, and are to be found on both sides of the Hindu Kush as well as in the basin of the Swat River, where they are known as Yusufzais. In the absence of anything approaching to reliable statistics I will not venture to give an estimate of their numbers, but, at a rough guess, I should put them at about one-fourth or one-fifth of the entire population of all that we call Afghanistan. It is with the Sirdars and the ruling caste of Kabul that I am best acquainted personally—the particular section of Afghan society which insists most strongly on its Israelitish origin. So far as education has prevailed in Afghanistan there are educated classes, but amongst them I have never met a man whose mind could rise above tradition and ritual, or who was capable of discussing an ethnological problem. They possess no history and no written records—the mullahs, or priests, amongst them being the only exponents of their unwritten laws and ritual. They are, of course, all Mohammedans of the Sunni sect, and as such they recognise the validity of the Old Testament; and there are certain curious traces of Levitical ritual in some of their observances—such, for instance, as the sprinkling of blood on the doorposts. But such slight evidence as exists of conformation to Israelitish custom and ritual would be quite worthless as establishing their claim to be true descendants of Jacob did it stand alone; nor do I imagine that their extraordinary capacity for the repetition of a genealogy which invariably ends (or begins) with Kish, the father of Saul, would be much more effective, although I am well aware that genealogies are by no means to be despised as evidence of origin amongst Orientals; because the recitation of a genealogy, passed down from father to son for generation after generation, is the main feature in traditional religious instruction. Apart from these genealogies the Durani can give no account of his origin except that he came from the west. The Turk (*i.e.* the Ghilzai) we know came from the north-east together with the Mongul; the Tajik (modern representative of the ancient Persian Empire) from Persia; but the Ben-i-Israel, differing absolutely in physical characteristic and idiosyncracy from all these, stoutly maintains that he came from the west, and he points to Rum, or Asia Minor, as his starting-point. We must leave it at that, and admit that from such very slight collateral evidence as we can attain he was undoubtedly an immigrant from the west. The absence of any satisfactory historical evidence need not surprise us. The early history of India is but a patchwork derived from the evidence of coins and inscriptions, the result of isolated discoveries. There is, indeed, no recorded history to which we can appeal. But whilst historical evidence is wanting there is another form of evidence altogether which is remarkable for its convincing strength, and that is the evidence of those physical attributes which are derived from heredity. The world is very, very old, and the earliest processes of differentiation in the physical attributes of mankind are lost almost beyond the region of speculation, but where the earliest dawn of tradition commences we find at once that there were widely separated communities—separated geographically, ethnographically, and physically—retaining an original impress acquired in the early days of evolution; and so long as these separate communities have preserved their race continuity unmixed, these hereditary attributes, as betokened by their outward appearance and character, have lasted undestroyed to this day. Indeed, the stamp of heredity appears to be indestructible. The Ethiopian has not changed his skin, nor the Mongul his obliquity; neither have the Semitic peoples of Western Asia lost their physical appearance which the sculptures of Nineveh have recorded.

Amongst the Semitic races the Hebraic cast

of feature and character is perhaps the most familiar and the most unchangeable of all, and no one can deny that the Durani Afghan– the true Ben-i-Israel—possesses it in a very marked degree. I once received a letter from the late Lord Roberts, who had read something that I had written on this subject, in which he said: "I am so glad that you think the Afghans are Jews. I have always been sure of it myself." As a matter of fact, I never thought that they were *Jews*, or said so; but the distinction between the Jew and the Israelite is one that is often missed. The Afghan hates the Yahudi —or Jew—and it is on record that Afghan authorities have even safeguarded Christians against the enmity of Jews in Kabul. Lord Roberts was impressed with the Hebraic personality of the Afghan, just as indeed has been every observer who has come into contact with him. Only a short time ago I was told by a lady who had lived in Jerusalem—whose father indeed is the Bishop of Jerusalem—that it is quite usual for parties of Afghans to visit the shrines of Jerusalem periodically, and that their Hebrew proclivities are at once recognised by other pilgrims. It was an Afghan who, not long ago, shot at some ill-advised tourists who interrupted him in his devotions at Jerusalem.

As a curious coincidence, if nothing more, it is, I think, worth noting that, whilst we may search in vain for an origin of the name Afghan (I have never been able to verify a statement which was made, I think, by the late Dr. Bellew, that it is an Armenian name signifying a mountaineer), there is no difficulty in identifying the name Kabul with that of the well-known place mentioned by many travellers in Palestine, the position of which was determined by the Western Palestine Survey. It was included in the lot of the children of Asher (Joshua xix. 28), and it was one of the cities which Solomon gave to Hiram (1 Kings ix. 13), who was by no means appreciative of the gift. Dr. Robinson, the American traveller, says of it that it formed the military base of the expeditions of Josephus into Galilee. In the fourteenth and fifteenth centuries it was a place of Jewish pilgrimage (note "Later Biblical Researches in Palestine," Boston, U.S.A., 1857). The identity of so peculiar a place-name in localities so widely separated as Syria and Afghanistan is at least curious, if not significant. If we are to concede the claim of the Amir of Afghanistan and of his Sirdars to be Ben-i-Israel (it is a claim that it would be most unwise to dispute in Kabul), it may at least be interesting to discuss the question how their progenitors could have reached the Kabul valley from Armenia, or from any other district "beyond the Euphrates" to which they were originally carried captive. This involves a cursory sketch, both historical and geographical, of the conditions which governed that vast upland territory which reaches from Mesopotamia to the farthest borderland of Afghanistan.

Apart from its academic interest, it is a subject of vital importance to us at the present time to know what lies between the Tigris and the Indian frontier, for events are gradually shaping themselves there which may ultimately affect our own destinies profoundly. We know that for centuries, since the Turk and the Mongul blocked the way to overland commerce between the Far East and the West, commerce has been forced, so to speak, into the sea. There was a time when, across the width of Persia, by at least two world-old high roads, the slow caravans passed and repassed, wearing deep ruts where the camels trod, bringing silks and spices and merchandise from Central Asia and India to Syria and the West. Then came the sweeping hordes of the north-east to interpose a barbaric wedge, which practically shut the main gates of the Eastern trade. European ships then began to find their way to India and China, and one by one, as rival competitors for the seaborne trade sprang into existence, success in securing the greater portion of that trade carried them to the foremost position in wealth and power in the Western world. Finally, England secured it, and has practically held it for two centuries, with what results we know. Let it never be forgotten what England owes to her trade with India. It was the very foundation of her greatness as a sea power.

Now, once again, does there appear to be in a not very remote future the chance of a revival of that old world honoured overland trade which existed before the days of Israel, which brought the treasures of the East to the marts of the West. There is abundant evidence before us that this desire of the nations—the acquisition of the highway to the East—is again a powerful force in international politics. Who can very well doubt that the centre of conflicting interest in the present war is gradually shifting eastwards and trending towards Constantinople (with all it stands for in the Mediterranean, in Egypt, in Asia Minor, Mesopotamia, and ultimately in Persia), as the final issue to be fought to a finish between Germany and Russia? Two notable events have lately been recorded in the

progress of Eastern affairs which bear directly on this important question of overland communications—they are signs of the times and portents of the future. The first railway has been opened in Persia. For the first time has the blue-coated agriculturist of Northern Persia stared open-mouthed at a locomotive bearing a huge national emblem traversing his fields. This is the Russian military line which connects Batum on the Black Sea with Tabriz. The other event is the piercing of the Taurus tunnel by the Germans, which will rapidly bring Constantinople and Bagdad into direct communication by rail, and place a rival enterprise on the Mesopotamian field.

Before discussing the interesting problem of modern railway extension, let us take a brief review of the past conditions of the country which lies between the Tigris and the Euphrates as it was in the days of Israel, when those highways were absolutely open to world traffic, though traversed by slow and leisurely methods.

Samaria was conquered by the Assyrians, and the Israelite tribes were carried into captivity about 721 B.C. This is a fairly well ascertained date. Sargon, the Assyrian conqueror, had not long been king. Five years before, he succeeded the usurper Shalmanesur on the throne. Shalmanesur, again, had succeeded another and greater usurper, Tiglath Pilesur III., who founded the last and greatest Assyrian empire about 744 B.C.

Assyria, in the days of Sargon, was therefore the empire consolidated by Tiglath Pilesur, and it is interesting to note of what that empire consisted in those early days. It was evidently an extension of previous empires which had included Asia Minor, and reached from the Mediterranean to the Caspian and the Persian Gulf, and there seems to be historical evidence that Tiglath Pilesur carried Assyrian commerce, if not Assyrian arms, as far east as Herat, Seistan and Kandahar, and even to the Indian borderland. Whether these remote provinces were ever an integral part of the empire may be doubtful, but it is probable that in the days of the Israelite captivity Assyrians knew their way well enough to Ariana (or Herat), and there is a curious tradition floating in the mists surrounding the early dawn of history that their commercial ventures extended still farther east.

From Herat I once travelled eastward through Afghan Turkestan to the plains south of the Oxus on the borders of Badakshan, in the midst of which plains stands the ancient capital of the Greek province of Baktria, now called Balkh. The modern town is founded on deep buried masses of ancient ruins, about which it is difficult to obtain any authentic information locally.

Ask any educated Afghan of that part of the world to tell you the tale of Balkh, and he will reply that it is the "mother of all cities," older even than the ancient Nineveh, and that its birth story is lost in those traditional mists which ascribe both Balkh and Nineveh to Nimrod as their founder. Why Assyrian rather than Greek tradition should surround Balkh is a mystery to me, unless indeed the very ancient connection between Mesopotamia and the Oxus plains existed even before the days of Tiglath Pilesur, and has impressed itself firmly and permanently on the popular mind. Tiglath Pilesur, as he appears in Assyrian sculpture—curled and anointed and seated on his throne—strikes the imagination as a great personage. He was undoubtedly a great warrior, and it is probable that, in all the width of the vast plateau which stretches from Mesopotamia to the Indian frontier, there was no one of equal strength and ability to dispute his sway—none to prevent the outward sweep of Assyrian conquest over those lands which even centuries before his time may have witnessed the passing to and fro of Assyrian commerce.

As we are now dealing with a region where geographical disposition of mountain and plain has shaped the destinies of nations from the very earliest dawn of history, and as the same geographical factors will yet again shape the course of a history as yet unwritten, it may be interesting to refer briefly to their chief characteristics.

The great plateau of Persia, overlooking Mesopotamia across rugged bands of Kurdish mountains on the west, is shut off from the steppes and highlands of the north by a continuous series of mountain systems, which stretch from Armenia to Afghanistan and beyond through the heart of Asia. But this mountain rim is for a great part of it narrow and easily passable, bordered on the Persian side by a continuous edge of grass land, through which runs the much traversed road connecting Tehran with Mashad and Afghanistan. There are important commercial towns along this route, but the value of it is largely discounted by the fact that the nomads of the steppes north of the mountains still carry their raiding enterprises (alamans) over the hills and into this grass land. South of the strip of cultivable country lie the great central salt deserts separating it

from the next important route traversing Persia from west to east, which starts from Bagdad, follows the old Median Way to Kermanshah, and then passes by Kirman to the Indian frontier. These are the two great important highways between Mesopotamia and India which are bound, both of them, to become something more than mere geographical features in a not very remote future. To the north of that mountain barrier, and extending eastwards and northwards farther than we can tell, in the early dawn of history there dwelt scattered clans of a vast Asiatic horde—Scyths and Sarmatians, of whom we have but a shadowy record. We know, however, that about the period of the Israelite captivity they were crossing the Don, already pushing their way westward towards Europe. I have more to say about them presently.

The geographical position of Nineveh also demands a short examination. South and east of Nineveh, hedging in the plains of Mesopotamia, are bands of wild mountain ranges, rank upon rank, forming a revetment to the Persian plateau, which are extended parallel to and facing the Persian Gulf and Arabian Sea to the Indus basin. They are full of uncouth and unconquered highlanders of many clans and various derivation, some of whom retain the names given them in the records of Herodotus, who wrote five centuries B.C. and about two and a half centuries after the fall of Samaria. Immediately north of Nineveh, where rise the sources of the Tigris and the Euphrates, are the mountains of Armenia reaching to the southern shores of the Black Sea. Through these hills eastward and northward lie those difficult routes, once open to Greece and Assyria, which now, in the process of historical evolution, are again open to military movement. The road from the north, dominated by Bitlis, and the road from the east, dominated by Kermanshah, which have both been in Russian hands, converge on Nineveh—or rather on Mosul, which is the modern representative of that ancient capital, and which is the chief centre of Turkish military activity in Mesopotamia. Thus once again does Nineveh assert the importance of her geographical site as one of the gates to Mesopotamia.

To turn once again to the Ben-i-Israel. The statement that the captive Israelites were transported from Syria to regions beyond the Euphrates is vague. Nineveh itself is beyond the Euphrates; together with all the valleys of the Upper Tigris and Armenia and Lake Van, Erzrum and Bitlis are all beyond the Euphrates so far as Syria is concerned—but Armenia is the country for which there is historical authority for locating them. This, however, is comparatively unimportant if we consider the statement of Josephus that seven centuries and a half later they were still a "great multitude" gathered beyond the Euphrates. So that it is only within the last eighteen centuries that they have become so scattered and absorbed by other tribes and races as to leave no trace of national existence. But doubtless the true Semitic spirit of the nomad possessed them and, like the Jews, they probably spread in small groups right through Asia. There is every reason to suppose that they did so. Unlike the Jews, they sacrificed their national cohesion to the lost faith of their forefathers, which had weakened long before they left Samaria. The rites and ceremonies of Jewish ritual, which are still so powerful a factor in maintaining the national unity of the Jews, had given place to strange forms of worship with a general tendency towards idolatry, nor was that federation of tribes which formed the Kingdom of Israel free from constant internal strife and disturbance. Thus elements of disintegration were deeply rooted amongst them.

There appears to be some confusion of thought as to the identity of the Captive tribes. According to Kitchener (who was a surveyor in Palestine long before he became a War Lord) it is impossible to define the former limits of individual tribes, but there is evidence to show that these limits had disappeared altogether in certain cases before the Captivity. For instance, the tribe of Simeon appears to have retained the nomadic instincts of the race and to have become assimilated with cognate tribes such as the adjacent Edomites and Moabites, only retaining certain holdings within the regions occupied by Judah. Simeon, you will remember, occupied the southern extremity of Palestine, south of Jerusalem, and reached down to Bir-es-Saba (or Beersheba), which is now the base for Turkish military activity in the direction of Egypt. The Captive tribes were, however, described as an "immense multitude" in the first century of our era by Josephus, and they were still "beyond the Euphrates." But as Josephus is the authority for the statement that a million Jews were destroyed with the fall of Jerusalem, and as this is an impossible number, we may perhaps discount the great multitude of the Israelites. There is nothing whatever to show that at this time (about the year A.D. 70, nearly eight hundred years after their captivity)

they were anywhere but in the position assigned to them by the early chronicles—*i.e.* beyond the Euphrates. Still less can we discover evidence that they had migrated in a body to steppe regions beyond the Black Sea and had become incorporated with the Skythic tribes who had then spread into Europe.

A few words about these Skythic nomads may be interesting in view of certain fantastic theories (accepted by thousands in this country) that they absorbed the Israelites, or that, in some inexplicable manner, the Israelites became Skyths. When the Greeks began to colonise on the north coasts of the Black Sea, about the time that Samaria fell, they encountered these steppe nomads as they gradually extended trade eastwards by a route into Central Asia which crossed the steppes from the Don to the Ural (about Orenburg), and thence carried traffic south-westward to regions between the Jaxastes and the Oxus beyond the Aral Sea. From the Don to the Ural the route mainly traversed the country of a kindred people called Sarmatians, but on the Oxus and between the rivers Skyths again prevailed. Thus they were to be found at intervals in regions extending from the Oxus to the Black Sea, and, indeed, it seems probable that they were still further west. They appear to have been first mentioned by Hesiod about 800 B.C., and by the time of the Captivity, 721 B.C., a good deal was known about them, as appears from the writings of Herodotus. They seem to have occupied all Wallachia, and the Dneister was Skythic as far as the Greeks knew it. They were an immense and widespread people, and with them certain European peoples trace an ethnographic connection, based (with some probability) on the similarity of the name Sakai with Saxon, and the known direction and extent of the Skythic irruption into Europe. The Skythic hordes invaded Medea and overran Western Asia about one hundred years after the Captivity, and, after extending their raids into Palestine, they finally destroyed Nineveh. Then, if ever, the Skyths and the Israelites met. But we know that the Skyths retired northward again and that the Israelites were still an immense multitude beyond the Euphrates many centuries after the tragedy of Nineveh's fall. There was no absorption then, and it is inconceivable that it should have occurred after the days of Josephus and the destruction of Jerusalem.

From the earliest days of prehistoric myth and tradition the expansion of the nomads from wide pastoral plains and steppes into the cultivated lands of the mountain valleys periodically changed the destinies of nations and renovated or rearranged humanity; but we never hear much of a reverse process which would spread the cultured people of the valleys away from their fields and their fixed habitations into the open land of the nomad. It is, indeed, almost inconceivable that any considerable tribal emigration left the valleys of plenty and of great natural beauty which lie beyond the Euphrates in the uplands of ancient Medea and Armenia to search for a home in the Southern Russian steppes. The assimilation or absorption of the Israelites by the Skythic tribes may surely be regarded as an ethnographical impossibility. We are confronted with many problems of international assimilation when we deal with national frontiers, but an absorption of one people of strong individuality by another of totally different physical attributes, leaving no trace behind, is practically unknown. I am reminded of the story told about Sydney Smith who, when he was reminded that there will come a time when the lion will lie down with the lamb, replied: "Yes, but with the lamb inside the lion." That, indeed, is descriptive of a process of assimilation which leaves no trace; but no vigorous and virile people have ever been swallowed up in this way. The incomprehensible but immutable laws of heredity prevent it. The impress of physical feature and of character inevitably recurs, sometimes continuously, sometimes after long intervals; but the result is certain, and, indeed, that result is often comparatively independent of numbers and based far more on character. No trace whatever of Semitic (still less of Hebraic) admixture seems to be recognisable amongst the Saxons of Germany, whose claim to Skythic extraction is difficult to overlook. This is what Hippocrates says of the Skyths or Sakai of his time: "They have stout, fleshy, flabby bodies, the joints concealed by fat, their countenances somewhat ruddy. They all looked alike. They lived on boiled flesh, mare's milk and cheese; they never washed, but enjoyed a narcotic intoxication in combination with a vapour bath. . . . The women daub themselves with paste, which they remove every second day." There is a certain irresist ble suggestion of the stout beer-drinking Saxon of modern Germany in this unflattering portrait of a great people, a suggestion which imposes the conviction that Saxon and Skyth are of one original race.

But, having arrived at the conclusion that the legal descendants of the house of Israel are not

to be found in Saxony (and still less amongst the Anglo-Saxons of Britain), and having expressed the view that a strong and virile race of people described as a great multitude in the first century of our era (and still to be found beyond the Euphrates) must have been practically indestructible, and believing, as I do, in the vitality of the Hebraic race of Israel as much as in that of the Jew, where are we to look for these descendants and inheritors of the promises made to Israel? This, indeed, is one of the greatest and most interesting of the ethnological problems of the world. I cannot pretend to offer any opinion of equal value to those of the many Biblical scientists who have investigated it. I can only humbly suggest that we might begin our investigations in those identical regions beyond the Euphrates (a definition which might apply to all the East between the Tigris and the Indus), starting with those districts to which historical evidence points as to their habitat after being carried away captive from Samaria: and the country which suggests itself first is Armenia.

Armenia is to us, quite apart from its ethnographic associations, a deeply interesting country, for we are here face to face with political problems of the future which may greatly affect our position in India. Armenia is not politically to be recognised as a nationality. It is not a kingdom, nor an autonomous state, but simply a wide mountainous region comprising the eastern provinces of Asia Minor to the south and south-east of the Black Sea, which form a western continuation of the great Iranian plateau. On the north it descends abruptly to the Black Sea, on the south it breaks up into rugged terraces which form steps to northern Mesopotamia, whilst it sinks more gently to the west to the lower plateau land of Asia Minor. The general average level of the floor of the Armenian highlands is about 6,000 ft., but the great barren ranges which intersect the country closely from north-east to south-west rise to 12,000 ft. They may be said to culminate in Mount Ararat, which is 17,000 ft. Between the ranges are broad upland valleys with narrow outlets for the rivers where they emerge from the plateau to lower levels south and west. Thus the chief roads through Armenia following the valleys afford that opportunity for military advance which is now being utilised by Russia. Directly northwards from Armenia there is no highway, the Black Sea and the Caucasus shutting off the country from the Russian steppes, so that the flow of human movement in this part of Asia has generally set southward and eastward into Northern Persia, to the south of the Caspian. Until lately Armenia was divided between Persia, Turkey and Russia; but the progress of the war has seen Russia in possession of the greater part of Armenia, and one may venture to prophesy that she will eventually dominate the whole. Such an event in the interests of the Armenians is to be most cordially welcomed, but we must at the same time not lose sight of the remarkable advance towards Russian dominance over the routes that lie between the Tigris and the Indus that is indicated by such an occupation. Clearly the new line from the Black Sea to Tabriz, of which I have already spoken, would be doubly safeguarded by its geographical position with regard to the Caucasian mountains to the north-east and the Russian occupation of Erzrum and Bitlis to the south-west. But this is not all, nor is it nearly all, the strategical advantage which a Russian Armenia suggests. Bitlis and Diarbekr dominate the Tigris, and they are within a measurable striking distance of the upper Euphrates in northern Mesopotamia. Here lies another problem of the future into which I will not enter.

Having thus sketched the position of Armenia, political and geographical, we may turn to the Armenians. The Armenians are a race so ancient that their origin is obscure. The proto-Armenian of the ninth century B.C. appears to have belonged to a tribal family which was widely spread over Western Asia, and which apparently spoke a non-Aryan language. Even in those early centuries there seems to have been a Semitic element amongst them of Assyrian or Hebrew origin. In the seventh century they were conquered by Medes and Persians, who introduced a fresh Aryan type amongst them, whilst it was during the same century that Israelitish captives were transferred from Samaria to "Calachene, Gozanitis and Armenia." There is, therefore, no difficulty in accounting for the strongly-developed Hebrew type which is now to be found amongst them. It must be remembered that only a minority (perhaps one quarter) of the inhabitants of Armenia are Armenian Christians, and the quality of the Christianity they profess depends on the Church to which they belong. There are Protestants and Roman Catholics, Greek Church, Gregorian and Nestorian, and they are as much divided from any ideal of Christian unity as they are divided politically or socially. They may number altogether some three millions, but

it is impossible to make an estimate of their recent losses under Turkish misrule. I trust that the numbers reported as having been destroyed are exaggerated, but they must have been very great. There is a great diversity of type amongst them. The Armenian of the country districts is described as thick-set, coarse-featured, with straight black hair and a long-hooked nose. The Armenian of the towns is more Aryan in appearance and more cultured. They are, however, essentially an Oriental people, the majority preserving the exclusiveness of the Jew and resembling the Jew not only in feature but in their widespread dispersion and tenacity of race. It is the Armenian of the Hebrew type who is scattered in isolated communities all along the northern route to Afghanistan and whom you may find in Herat, although I never met one to my knowledge in Kabul. On the whole, the Armenians are not an attractive people. They may be sober, industrious and intelligent (they are remarkably keen and acute in business matters), but the truth is not in them, and they have no idea of national unity; the men of the plains being usually set against the men of the hills as in the days of primitive humanity. We need look no further for the racial impress and hereditary characteristics of Captive Israel. Most of the Armenians I have met might have come fresh from Samaria, and their conversion to Islam and to Christianity has done little or nothing to modify the ingrained Hebrew type.

There is no difficulty in accounting for their dispersion through Asia. As far back as we can see into the dim past that heralded the dawn of history, we can faintly discern the movements of great multitudes of people over the face of Western Asia, a constant procession of restless humanity struggling and reaching after a better place in the sun than that afforded by ancestral pasture lands; or it may be a vast commingled mass of various nationalities co-ordinated and drilled into army shape by the will of some potentate more mighty even than a German Emperor, moving with the tramp of millions of feet to overwhelm all smaller states in order to amass one huge loosely consolidated and far-spreading Empire. Again, it may be a weary band of captives transferred from a captured town at one end of the empire to develop some great scheme of city building or irrigation at the other. That the Samarian captives should be transferred to lands just beyond the Euphrates was nothing. They might easily have been transferred to lands as far beyond the Euphrates as are the plains of the Oxus about Balkh or even the Indus valley. Thus dimly in the twilight before the dawn we can discern the ebb and flow of a steady commercial tide between Nineveh and Balkh. This may have either preceded or followed the conquest of Persia and of regions contiguous to the Indian frontier by Assyria. Then (or perhaps even before the days of Assyrian conquest) occurred the outward spread of Greek enterprise from the Black Sea colonies to the Hindu Kush, which left Greek settlements amongst the northern foothills of that range and a remarkable colony at Nysa in the wild hills north of Peshawur. This colony, you remember, claimed the primeval leadership of Dionysos and a kinship with Alexander the Great when, centuries later, he invaded the plains of the Punjab. But before the days of Alexander the Persian Empire, under Darius, had claimed all that Tiglath Pilesur had fought for, and it is here and during the period of Alexander's expedition that we touch the first steps of history. We have to thank the father of history, Herodotus, for a very careful geographical compilation which tells us the names of the Far Eastern Satrapies under Persian rule, and refers by name to tribal communities which we can recognise still in their ancient mountain habitat. In those restless days when people were not overburdened with a multitude of goods, when there were no frontier landmarks between the Tigris and the Indus, and all Persia was open to the nomad, it would be most surprising if a restless people like the Israelites did not either, as captives or free agents, spread eastwards in companies in search of a promising field for commerce or employment. There is therefore no inherent improbability in the claim of our Afghan friends to be one such community that has preserved itself comparatively intact through the centuries, like the Jews, or that they should claim a direct descent from Israel.

Thus far our inquiry into the origin of the Durani Afghan has led us to consider, as a subject of more or less academic research, the historical and geographical conditions, human and physical, of that old time-worn and well-trodden region between the Tigris and the Indus which has seen great empires and dynasties rise and fall, and which is now relegated to a position amongst the nations which admits of no pride of race, no military importance—nothing but economic poverty and administrative incapacity. The rights of the highways through Persia, if not Persia herself, have become the desire of

Western nations, and we hear loudly-expressed political aspirations for the open "road to the East." What does the East mean? Does it mean Persia and Central Asia, or does it mean Afghanistan, India, and China—or all of them? I think we may take it that it undoubtedly means India directly and the rest ultimately. I have already drawn your attention to the fact that the iron rails of two great systems emerging from Europe now point eastwards, and that neither of the two belongs to England. One is Russian from the Black Sea, the other is German from Berlin and Constantinople. We, in our small way, never consider any great political or economic proposition except from the standpoint of its immediate effect and its possibilities in the near future under conditions which we gauge by the present. In the matter of a straight overland connection with India we have done nothing, just as in the matter of undersea connection with the Continent we have done nothing. We have waited to see what others might do. We have not completed the easy link with Herat from the Indian frontier, and in the matter of Persia we have been contented with interminable surveys and projects. Paralysed in India for fear of Russia, paralysed (so far as the Channel tunnel is concerned) by fear of France, we have lately been paralysed by fear of Germany and her designs on Bagdad, and we live in hopes, not so much that we shall defeat them, as that our once mistrusted but now well-loved ally, Russia, will do so. Let us hope that the war will shake old England out of her paralysis, and that we shall take our place once more in the world of international enterprise. Anyhow, Asiatic developments will not stand still for us, and I can foresee the time when not one but several open lines of railway will traverse the Persian uplands, and, possibly, the Persian seaboard, too. Then, perhaps, may economic wealth redeem the country which is pre-eminently agricultural, and then will Persia possibly once again rise to importance. But I am not concerned just now with any political problems affecting the Persia of the future. I only wish to indicate what may be done by Russia or Germany, if not by ourselves, in the matter of developing through lines of communication in that country which may ultimately reach our Indian borderland.

Few of us here have any doubt of the value of India to us as an Imperial asset. Probably our methods of administration do not meet with the admiration that they deserve from foreign critics, and we can easily imagine a far more drastic scheme of utilising her resources, both in men and material, than our own were the mastership of India to change hands. Would the Germans, for instance, be content with half-hearted and spasmodic schemes for industrial development? Believing as they do, in a military basis for all schemes of expansion, would they, with a population of 300 millions to deal with, be satisfied with a small army of 150,000? Would they permit a physically weak and unmilitary caste to sow sedition broadcast and to tamper with that army? Would they not, by any means in their power, by education and by propaganda, bind the ignorant masses of India to a blind faith in their Heaven-appointed mission as rulers until German hymns were sung from Cape Comorin to the Himalayas? India, with its traditions, its wealth, its immense possibilities, will always be a potent influence in directing progressive action towards the East, and in such measure as we value India must we watch the trend of railway expansion from the West. It seems probable that either Russia or Germany will dominate Constantinople after the war. We trust and we mean that it shall be Russia. We need not examine closely into the nature of that dominance, but we may regard all the Balkan fighting and all the struggle in Asia Minor as but the preliminary to a decision on the final question of command in Constantinople with all that it stands for in Asia Minor, in the Mediterranean, and in Egypt. There is, however, this difference between them. Russia without Constantinople has still a wide vista of national expansion, if she retains Armenia. Germany, if she loses Constantinople, loses all her hope of Eastern progress.

Let us look at Russia's opportunities first. From Julfa, on the Aras, where the boundary between Russia and Persia is crossed to Tabriz, is only ninety-three miles; Tabriz being, perhaps, the most important commercial centre in Persia, with a great trade in carpets, cotton, dried fruits, etc. Moreover, Tabriz is, or will shortly be, in direct connection with the great agricultural districts round Lake Urumia to the west, and by its connection with Tiflis it becomes an important branch of the whole great Russian railway system. We may be well assured that this important innovation into Persian territory was not undertaken for the sa e of bringing carpets and raisins to the Russian market. We may indicate Tehran as the immediate military objective where railway extension will support the long-considered scheme of Russian domina-

tion throughout Northern Persia. To Tehran there is about 350 miles of somewhat narrow mountain approach under the shadow of the Elburz ranges; but it is a well-known route, carrying a telegraph line, which encounters no greater obstacle than one comparatively low watershed (I do not know the exact height of it) and a bridge over the Sefid Rud, before reaching the important town of Kasbin, about one hundred miles short of Tehran.

From Tehran there opens out at once a magnificent prospect eastward—perhaps the greatest that the Eastern world affords. The military domination of all Northern Persia would be incomplete without the support of a railway skirting on its southern side the great mountain system which reaches from south of the Caspian to the western borders of Afghanistan. We may take it for granted that the necessary line will follow, backed by Russian energy and capital. If it follows the old trade highway to Shahrud, Bujnurd, and Kuchan to Mashad, it will not only tap, and at the same time develop, the resources of a most fruitful district of Persia, but it will set an end to the raiding proclivities of the Turkman horsemen who still, from time to time, harry the open grass lands south of the mountains. From Mashad (about 550 miles from Tehran) will follow an inevitable 100 miles of mountain line to a junction with the trans-Caspian system on the north, and the almost equally certain extension to the extreme Russian frontier post near Kushk, eighty miles north of Herat. Whether it will eventually reach the Oxus plains about Balkh and join up with that further branch of the trans-Caspian system which is expected to link Bokhara with Termez on the Oxus (just north of Balkh) is at present on the knees of the gods, but there is nothing to prevent it except the susceptibilities of Afghanistan, and in the fulness of time it may be looked upon as an almost certain issue. Equally certain in the long future (perhaps not so very long) is the connection with India. The connection *viâ* Herat, easy as it is, has often been discussed and as often dismissed from the category of immediate possibilities on account of the interposition of Afghan territory and the direct opposition of the Amir to railway extensions in his country. It is, however, not necessary that either Russia or we should trouble the Ben-i-Israel in this matter, for there is no insuperable obstacle to a connection *viâ* Birjand and Seistan, to the west of the Helmand River, a connection which would open out local commercial prospects which might eventually go far towards justifying the expense of maintenance. This, however, is not the only nor perhaps the best of the splendid opportunities open to Russia for Persian development and connection with India. So far we have dealt only with what will prove to be an essential condition of Russia's domination of Northern Persia—*i.e.*, the line from Tehran to Mashad. That will inevitably take the precedence of any more purely commercial enterprise as a necessary strategic condition. And here I may perhaps be permitted to record my opinion that Russia's control of Northern Persia will be greatly for the benefit of the country and of the people, who will thus come directly into contact with her methods of civilisation. Russia's goods will flood the markets, and Russian traders will compete with Armenians and Persians in these busy marts; but the great gain to Northern Persia will be security and peace. Nor need we in the least fear the results of this acquisition of a new frontier to Russia, which has long been her natural heritage from its geographical position. Here it is not the Elburz system—which is readily crossed by the raider—but the vast salt midland deserts which form the best natural south-western horizon to Russia's trans-Caucasian provinces. The other obvious opportunity to Russian enterprise is a line from Tehran southwards to Kashan and Isfahan, and thence through the great commercial centres of Yezd and Kirman to Baluchistan and India. Such a line as this would be the making of Persia. Whoever builds this line holds Persia in his hands, and must exercise paramount influence on her destinies. It is Persia herself who should construct such a line as this, and secure for her revenues the enormous advantage of a great through mail service between Europe and the East.

Just what I have so lightly and so inadequately sketched may indicate Russia's position in that contest for the highways to the East which she is undoubtedly waging at present. Germany's position is perhaps not quite so clear. Absolute dominance in the Balkan States and in Turkey is the basis of it all, and the open line to Bagdad is the inevitable sequel which appears at present to be well within her grasp. But what beyond Bagdad? It is, I think, sufficiently clear that she might have visions of a line passing up the old Median Way to Kermanshah, and thence extending itself along that upland road which I have already pointed out as passing by Yezd to Baluchistan. But I very much doubt if any such ambitious programme was ever regarded as

a probable, or even possible, result of a Bagdad occupation. She might, again, look to lower Mesopotamia and an extension to Basra, thus securing for herself not merely the upper half but the whole wealth of the rich Mesopotamian plains when Sir William Willcock's great irrigation scheme ripens into an accomplished fact. That, indeed, would eventually amply repay the outlay on the whole project. It would be a magnificent contribution to the Eastern world's development, and it would bring Germany to a seaport at Basra. That, again, does not seem (so far as any indications as yet presented to the public are trustworthy) to be her present ambition. It brings her into direct conflict with Britain. The line to Bagdad in itself would sufficiently tap the broad wheat and cotton areas, and would go far to drain our Basra trade dry without any excursion southward. Moreover, when Germany makes a bid for Eastern commerce you may take it that her ambitions are wholesale and far-reaching. It is not merely Mesopotamia and Persia, or even India added, that fills her horizon. You must also add China, and remember the millions that she has already sunk in securing a footing in that Celestial republic (if it is a republic). That is perhaps why, in days before the war, it was not Basra that figured in German propositions, but the port of Kawait, south of Basra, commanding the seaway to Basra, and untrammelled by a long shallow-river approach with a bar and bottom of mud. That is perhaps why in these days, when any faint suggestion is made of the peace terms that would suit Germany we always hear that England is to give up control of the sea. What does it mean? The North Sea and the Atlantic have ever been open to German shipping. Many of us have traversed the ocean in Hamburg-Amerika liners and found them comfortable enough. Her ships have been able to come and go as they please. But she has not been able to plant coaling and, incidentally, submarine stations on any coast she pleased, nor has she obtained a port in Eastern waters between Suez and China. Here, I believe, we have the true explanation of German ambitions as regards Eastern trade—ambitions which would involve a direct threat to Indian traffic if not to India herself (for we must remember that India is far more vulnerable by sea than she is by land). This consummation of her hopes is for us to deal with—not for Russia—and the consideration of it brings us back to a fuller appreciation of the meaning of political domination in the Balkans and Constantinople and, finally, of that command of the sea which is our heritage, and which is far more to us than any conquests or expansions by land that we are ever likely to contemplate. We have, however, rather drifted away from the Tigris and the Indus whilst following out this brief consideration of the "road to the East," the command of Eastern trade, which has become the dominant factor in the war.

In conclusion, I would suggest that, apart from these war questions, which are necessarily of vital and immediate interest to us, there is ample and most interesting opportunity for inquiry and research into the academic fields of the history and ethnology in the regions which lie between the Tigris and the Indus. There is, I hope, a prospect that opportunity for such investigation is not far distant. We want to know more than we know at present of the Armenians and their records as well as of the Ben-i-Israel; and we want a closer geographical knowledge of all that lies between Herat and Kabul. Above all do we want a scientific examination of the site of the city of Balkh, which would surely yield results of importance and historical interest such as would rival even those of Nineveh. As for the field which presents such thorny problems to European politicians now, and which will inevitably in the not distant future be subject to the impress of action, political, military and commercial, which will frame new pages of history—the lands which lie between the Tigris and the Indus, and the right of way across them—I have endeavoured to show you that at one end of it lies Armenia and the hills beyond the Euphrates, and at the other the land of a strong and self-contained people who believe themselves to be Ben-i-Israel. In Armenia it seems to me are still to be found the evidences of Hebraic survival which might easily be traced to the lost tribes of 1800 years ago. The Armenians may be but the dregs of a once great people and anything but pure in lineage, but the Hebrew characteristics are still predominant. Over these people is rapidly spreading a new and Christian domination in the shape of Russia, and under Russia we may confidently hope that the hard-tried Armenian will eventually rest "quietly and peaceably governed," and once again lift up his head. Scattered along the highway to Afghanistan are isolated communities of Armenians, holding themselves distinct from their Persian surroundings, engaged in trade, the men with a leaning towards horse-dealing and the women workers of wonderfully fine silk embroidery much

appreciated by the Kabul aristocracy. The Armenian schools are said to be excellent, but I have never visited one of them. At the Afghan end of the highway we find the Ben-i-Israel, strong and amazingly self-confident, calling themselves by the old names Ibrahim, Ishak and Yakub, and holding the gates of their enemies—the passes of the Hindu Kush and of the Indian Frontier—with grim determination; a truly important people—the dominating tribe in a great kingdom. Their King Habibulla is a strong ruler and an astute statesman. His speech to the Mohammedan leaders in India gathered within the walls of the great Mo que at Delhi on the occasion of his visit to India, was, for eloquence, for direct good sense and tactful diplomacy, equal to some of the best efforts of his European contemporaries and far superior to most of them. Habibulla may well be regarded as the warden of our Indian Marches during this great war. It is a sure thing that our turbulent neighbours on the Frontier think much more of the Afghan Amir than they do of any British Commissioner since the days of John Nicholson; and, although we have had our rontier troubles since the war began, there is no suspicion that the Amir has been other than a good and useful ally to us, disdaining the overtures of our enemies, whilst treating them with true Afghan courtesy and hospitality—so long as they were strangers within the gates. As the war winds on, and slowly one by one we gain those points of vantage which will ultimately lead to victory, I think upon the old battle-cry of the Hebrews, which must have often echoed over the hills of Canaan as Joshua led his hosts to victory—"Isra-el, Jehovah fights for us."

DISCUSSION.

The CHAIRMAN (Lord Bryce) said the Society was deeply indebted to Sir Thomas Holdich for a very valuable paper from which they had all learned much. He had given a singularly fresh and vivid account of the physical features of several of the regions he had dealt with, and had also suggested many ethnological questions of great nterest. The most interesting bore upon the possibility that the Ben-i-Israel of Afghanistan might have some basis for representing themselves as the offspring of part of the ten tribes who were carried away, according to the record in the Book of Kings, by Shalmanesur, or by Sargon. The aspect of the few Afghans he had seen round about Peshawur and elsewhere in North-West India led him to agree that certain of the features which were attributed to the Semitic race were also to be seen among the Pathans, but he was not so sure about the alleged resemblance between the Armenians and the Ben-i-Israel. The type of Armenian face seemed to him to differ in its most characteristic features from the Semitic type. It was much more like the Kurdish type, and he thought the most probable view was that both the Kurds and the Armenians belonged to a mixed race, largely Iranian. Both spoke languages of the Iranian group. Having known a very large number of Armenians, he had been greatly struck, not only with their high level of intelligence and industry, but also by their intense patriotism. He did not know of any people who had shown greater constancy, patience, and patriotism under difficulties and sufferings than the Armenians. He personally had always found them perfectly loyal. He had frequently had occasion to give them confidential advice and to trust them with secrets, and never on any occasion had he found that confidence misplaced. Everybody was now agreed that whatever happened at the end of the war, they must be for ever delivered from the oppression they had suffered which had culminated in the recent frightful massacres. As a proof of their loyalty and devotion to their country he might mention that the Armenians living in America had contributed sums enormous in proportion to their number and resources, for they were nearly all persons of small means, for the relief of the refugees who had been driven out by the Turkish massacres. No people during the war had done more in proportion to their capacities than the Armenians had done for the relief of their suffering fellow-countrymen. A large number of them were also fighting as volunteers in the armies of France, where they had displayed the utmost courage and valour in the combats before Verdun. The author had raised a very curious question as to whether the Skyths were connected with the Saxons through the name Sakai. In his own opinion analogies or arguments based upon names were extremely doubtful. For instance, there were three sets of Albanians in different parts of the world—the ancient Albanian people of the Caucasus, the Albanians (who called themselves Skipetar) of the Balkan Peninsula, and, in the third place. Alban was the ancient Celtic name of Scotland. There was no reason to suppose that any one of those three names had anything to do with the others. He desired to join in the tribute of praise accorded by the author to the fine qualities of the Afghans. They were a remarkable people, of great natural gifts in many ways, for whom there ought somehow to be a great future. Probably many of those present knew that their ballads possessed high poetical qualities. An interesting account of these would be found in the book of a distinguished French scholar, James Darmesteter, called "Les Chants populaires des Afghans." Lastly, the author

had dealt with a most important question regarding the great lines of railway which were likely to be constructed and to become of political as well as economic consequence within the next twenty, thirty, or forty years. There could be no doubt that two or three lines would be projected to connect the West with the East, but the author had not mentioned the possibility of a line running along the north coast of the Persian Gulf through Southern Baluchistan to Karachi. He understood there were extreme difficulties to be faced on account of the aridity of the climate, but it must be considered as an alternative or additional line to the two northern ones which had been referred to. The author had indicated his belief that one of the goals of German ambition was the possession of a port on the Persian Gulf. He (Lord Bryce) ventured to express the opinion that when peace came to be made the Allies ought to declare their purpose not to allow Germany to obtain any hold upon Mesopotamia or anywhere in those regions. The projects of Germany which had come to our knowledge showed sufficiently how dangerous it would be to our own interests in India and to the security and well-being of those countries themselves if those designs ever had a chance of being fulfilled. He subscribed heartily to the hope expressed by Sir Thomas Holdich that Germany would on no terms be allowed to acquire Constantinople. Constantinople was of the utmost importance, not only from its control of the Ægean Sea and the ports of the Mediterranean, but also because of the route it opened up from Asia Minor to Mesopotamia. It was in population no more Moslem than it was Greek or Armenian, so there was no infringement of the principle of nationality in extinguishing there the abominable rule of the Turks. He thought it might be taken for granted that one of the points upon which the Allies were most united and would be most firm was the prevention of any hold whatever being established by Germany in the Balkan countries.

[The chair was then vacated by LORD BRYCE and taken for the remainder of the meeting by SIR WILLIAM DUKE, K.C.S.I., K.C.I.E.]

DR. M. GASTER said he belonged to a school of old memories, and the views which he held in regard to the development of the Near Eastern problem might differ from those which some of those present cherished, because he might look upon the developments in a light which did not tally with modern tendencies as the result of the terrible times through which we are passing. The author had shown how uncertain rule had been in certain parts of the world. It might be taken as an axiom that no nation of the West could ever retain permanent domination over the East. The nations of the West might, perhaps, obtain political power and exercise some economic pressure; they might use the East for the purposes of their own enrichment and development; but how much of the East had yet benefited from the influence of the West? Only those could reply to the question who knew the history of Asia Minor or the whole of the East except India, which came under the direct domination of Britain and which was not considered as a place of exploitation, but had benefited by the beneficent rule of an ancient tradition and civilisation. But for the rest of the East there had been nothing but ruin and desolation. A stirring was going on through the nations of the East, and some believed that the result of the war would be a most unexpected one, which would not be realised in a day but possibly in our own generation. A new life was dawning, and the Eastern nations, profiting by the lessons of the West, would probably derive a new impetus and would come back to life in a different manner than some people supposed. The Arabs, the Moslems, and even the Persians were stirring, and he did not know whether any domination from outside would be helpful to their internal emancipation. The Society owed a profound debt of gratitude to the author for the highly instructive part of the paper dealing with the romantic side of ethnology. The Ben-i-Israel of Afghanistan might unquestionably be considered as the last representatives of some of the tribes of Israel that started migrating East even before they were carried away by Shalmanesur or Sargon into captivity. The present was not the place to discuss the mission carried out by the prophets of old, but there was no doubt there had been an intimate connection between all the nations from Palestine, even from Egypt up to the Indus, and perhaps further east as far as China. In his opinion the descendants of a good many of those who were carried into captivity were now living there in modern times as Mohammedans, and the doubt which Lord Bryce had cast upon the admixture of the Hebrew element with the Armenians was, perhaps, unfounded. His own knowledge of the Armenians was not so profound as that of Lord Bryce, but he had come in contact with a great many of them. He could not deny that they had very pronounced Hebrew characteristics and features in their manners, clannishness, charity, and even quarrels. There was some peculiarity about them which, in many ways, reminded one of the Hebrew characteristics, physical as well as mental. It was known, not only from Josephus, that a large number had been living there from the time of Sargon, but that the Seleucid Kings had transferred from time to time large colonies because they used the Jews as soldiers; they did garrison duty all along the frontiers of the Empire. The Jews seemed to be the most trusted soldiers. Papyri which had been discovered in Egypt proved that there was a

Jewish garrison there holding the country in the name of the Persian King. Only the Jews had been able to survive in Asia; no European settler except a small colony had ever been able to prosper; all attempts at colonisation from the West had been fruitless. It had been proved in regard to settlers from the West in Palestine and Syria that within two generations German, French, and English settlers had degenerated. The same was the case in India. The same thing happened with the German colonists in the Holy Land. On the other hand, the Jews who settled in those countries became entirely transformed. The very history of the spread of Christianity could not be understood unless it was assumed that there had been large Jewish colonies throughout the eastern parts of the world. The ancient Apostles never went to the heathen; they went to their brethren in faith, and preached the Gospel to them. It was impossible to understand the story in the Acts of the Apostles and in the Apocryphal Gospels unless it was assumed that in those places to which they went to preach the Gospel they went to their own brethren—to the Jewish population, the Israelites, and the Judaeans; otherwise the whole spread of Christianity would be a greater mystery and a greater miracle than it was at present. That pointed to vast Jewish populations scattered throughout the ancient Babylonian Empire and fully justified the assumption of the author that he saw in the Afghans the last representatives of the ancient Jewish settlers from Samaria and Judaea.

Colonel C. E. Yate, C.S.I., C.M.G., M.P., said he believed most fully that the Ben-i-Israel of Afghanistan were real *bonâ fide* Israelites. He had lived with the Afghans month after month and year after year, and had seen how their souls were possessed with the one great tradition that they were the Ben-i-Israel, and why anyone should try to deny them their heritage he could not understand. The author had brought home to them how the great fight would have to be fought to a finish between Germany and Russia for Constantinople. One or other of those two Powers would have to possess it, and the question of its loss to Turkey was agitating the minds of Indian Mohammedans at the present moment, but he did not think they realised yet what it meant to India. Indian National Congresses and Indian Moslem Leagues had passed resolutions asking for political concessions, in view of the magnificent way in which the Indian soldiers had fought in the present war, but not one of the speakers had taken any actual part in the fighting. It would be much better if those Congresses showed the people of India how the whole of the welfare of the country depended upon who possessed Constantinople in the future, and how necessary it was for them to pledge the whole resources of India in men and money for the successful prosecution of the war. If Germany was the conqueror in the present war and became a world-wide Empire in the future, it meant that India eventually would come under the iron heel of German despotism, and there would then be no place for National Congresses. India had not yet wakened up; it was necessary to explain to the leaders of Indian opinion what the war really meant to India and what might happen to India if Germany came out on top. On the other hand, if Russia obtained Constantinople the great trans-Continental routes across Northern Persia from east to west would be opened up; railways would be made from the Black Sea across to Tabriz, Teheran, and Meshed, and further east towards China. By so doing, Russia would add largely to the security and safety of Persia, the Persians would greatly benefit at the same time, and India would not be touched. The real boundary in future between the spheres of influence of Russia and Great Britian was the great salt desert in Persia. Russia should build all the railways to the north of that salt desert which ran across the centre of Persia, but all to the south should be the British sphere of influence, the present neutral sphere being abolished. If Germany came out victorious it meant, not only that Constantinople would pass to Germany, but that the Baghdad Railway would be completed and the British control of the sea would be destroyed. Germany cried out for the freedom of the seas, but that would eventually mean that Britain, which had policed the Persian Gulf, the Indian Ocean, and the Red Sea for the last hundred years, at great cost, would be wiped out. Germany would have the freedom of those seas, and the ultimate aim of Germany would be the conquest of India. The Amir of Afghanistan, whom he regarded as a most faithful ally, had kept the whole of his country quiet during the war, and if he was well advised he would remain as he was, and not open his country to railway enterprise till all wars and rumours of wars had come to an end.

Mr. Douglas W. Freshfield, in proposing a vote of thanks to Sir Thomas Holdich for his valuable paper, said that one point had not been adverted to in regard to the identity of the Afghans with the Ben-i-Israel — viz. that in no other part of the world were the Jews the dominating ruling and military caste as he understood they were in Afghanistan.

Sir H. Evan M. James, K.C.I.E., C.S.I., in seconding the motion, regretted that the author had not taken the Ben-i-Israel far enough east to a very curious old habitation of undoubted Israelites and Hebrews to be found to this day in the centre of China, showing how the ancient Hebrews wandered about the world.

The resolution was carried unanimously.

SIR THOMAS HOLDICH, in reply, said that no one knew better than he did the fallacy of drawing the analogy between names, to which Lord Bryce had referred. It did not follow that because the ancient Skyths were called Sakai and the modern Germans were called Saxon that they were connected. There were other reasons which he was afraid he had not made sufficiently clear in his paper. History was quite clear that the Skyths were, at the time that he had been dealing with, making their way towards Central Europe; and it was also tolerably clear, from what Hippocrates said, that the ancient Skyth was exceedingly like the modern German in physical constitution. It was not merely the analogy between the names that he trusted to.

THE RT. HON. SIR HENRY MORTIMER DURAND, G.C.M.G., K.C.S.I., K.C.I.E., writes:—The derivation of the word "Afghan," as explained to me when I was in Kabul in 1879, is from Picah, a leader of the Ben-i-Israel, who led an Israelite swarm to Herat. His people were called Picahani, whence, by corruption, Apicahani, and so Afghan. But Oriental derivations are bold.

EIGHTH ORDINARY MEETING.

WEDNESDAY, JANUARY 31st, 1917; COLONEL SIR THOMAS HUNGERFORD HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Chellew, George, 99, Chevening-road, Willesden N.W.

Davis, William Alfred, Pusa, Bihar, India.

Robb, Captain William James Paulo, A.O.D., c/o Sir Charles R. McGrigor and Co., 39, Panton-street, Haymarket, S.W.

Stone, Judge Kimbrough, Kansas City, Mo., U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Boag, George L., Aguilas, Murcia, Spain.

Lovejoy, Frank W., 1433, Main-street, Racine, Wisconsin, U.S.A.

The paper read was—

WITH THE Y.M.C.A. IN FRANCE.

By ELLA C. SYKES.

Everyone knows that there are many temptations lying in wait for our splendid soldiers both abroad and at home, and the Y.M.C.A. has done and is doing a splendid work in coping with them.

The Red Triangle symbolises a helping hand stretched out to every soldier irrespective of his creed, and in the Y.M.C.A. Hut religious and social differences are laid aside. The Church of England Padre and the Jewish Rabbi, the Roman Catholic Priest and the Nonconformist Minister, are made equally welcome when they wish to hold their services, for the main object of the Hut is to be a counter-attraction to drink and dissipation, and if anyone in my audience is in doubt as to its usefulness I will merely remark that in one place in France the Town Major affirmed that the advent of the Y.M.C.A. had meant a reduction in crime of 80 per cent.

During my stay across the Channel there were no fewer than 171 Y.M.C.A. centres in France and Flanders, some being within a mile of the German trenches. One hut had been destroyed by shell fire, and in another a dug-out had been provided for the workers as their hut had already been "wounded" no less than fifty times. I was told of one worker who had had a narrow escape. He was talking with three soldiers outside when his companions were killed instantaneously by a bursting shell. He himself, though hurled across the road by the concussion, escaped without a scratch, but naturally suffered from shell-shock.

The huts are all portable and built in sections, in order that they may follow the army as it advances, but here and there other buildings have been taken for the work, such as an old church, a convent, a mayor's parlour, a cinema hall, and so on.

Princess Victoria of Schleswig-Holstein had started a scheme by which women could do canteen work in these huts in France, and I was fortunate enough to be able to do such work for three months.

I had a certain amount of adverse criticism from my friends, who considered that I might be more usefully employed, and I confess I had a few doubts myself. However, the first soldier who told me that the presence of women workers made the Hut "a bit of home" exorcised them for good. The scene of my labours consisted of two huts, one reserved for services and entertainments and the other having a long counter at one end with lockers underneath containing the different articles, numbering about a hundred, that were sold by the Y.M.C.A. to the soldiers. Two officials managed the place, did the accounts and so on, but we women were allowed a free hand at the counter, and the first duty of a newcomer was to learn the price of everything and be able to lay her hand on it automatically.

Halfway down the hall was the cash desk, where penny tickets were issued, and across the room the tobacco counter made its appearance later on, proving a boon, as it diverted much pressure from the end counter.

We worked between seven and eight hours daily in the Hut, motoring to and from our temporary home, a quaint little villa on the sea-front, where I shared expenses with three other women workers.

A short time after my arrival we had the proud distinction of beating the record of any other hut in France, 2,800 francs, or 28,000 penny tickets, being taken in one day. This was a strenuous time for the workers, as the calls upon us were unceasing, the Hut being thronged with a tightly-wedged mass of men from almost every British regiment, who struggled with one another and fought good-humouredly in their efforts to reach the counter. The crush got greater as the afternoon wore on, and often between two or three hundred of the long French loaves would be consumed in the form of bread and butter.

The huge supply of sandwiches that we had made during the comparative lull of the morning, the numberless hard-boiled eggs, and the many dozens of cakes from the pastry-cook were soon devoured, and we would take turns to cut up scores of the currant cakes imported from England, each block having to be divided into forty-eight slices, and we would empty the cases full of "dollies," "jollies," and "gingers," piling them on to large dishes, or fill baskets with penny or twopenny packets of biscuits.

In one of the cases the workers found a letter from a girl packer offering herself in marriage in the most bold-faced way to any soldier who might come across her missive. We have often been told that the postscript is the most important part of a lady's letter, and this one was no exception to the rule. In it the girl mentioned that if the warrior happened to be married she hoped that he would be a "dead sport" and hand on her offer to any bachelor friend!

The question of supplies was often a difficult one, as the main bulk came from England, but our Hut was seldom short of food or tobacco; and I was not surprised to hear that it was no uncommon thing for the Y.M.C.A. Commissariat in France to handle two thousand cases of provisions in a day.

Our customers had usually a deep-rooted objection to giving the whole of an order at once, and the worker had in consequence to race up and down the counter perpetually to supply their needs.

For example, a little "Bantam" from Glasgow would demand a "brad" with a frown as he held up a ticket, and when this was procured he would curtly remark "anither," and the worker would have to run back again to the huge basket full of buttered slices. A finger would then be pointed imperatively at a custard tartlet ("dead hands" the men called them among themselves), or a vanilla sandwich (dubbed a *religieuse*, or nun, by the pastry-cook) would be required. Probably such articles as bootlaces, an indelible pencil, fags, "bachelors' buttons," or toffee would be demanded one at a time and paid for separately, the customer having a peculiarly brusque manner and ignoring such social amenities as "please" or "thank you." I found "broad Scots" somewhat trying now and then, until I grasped that by "cannel" a candle was meant, though it was very easy to confound this with "caumel," signifying a packet of caramels. I earned the contempt of one customer when I handed him a tin of boot polish in response to the word "nugget." He scornfully rejected it, and, instead of explaining what he wanted in other words, he asked in louder and louder tones for "nugget," until a Southerner came to my aid and explained that "nougat" was desired. Perhaps my most crushing experience was on one occasion when I was helpless at the request for a "bawbeen" (by this a reel of cotton was meant). My Jock remarked in scathing tones, "And I spak' to ye in plain English"!

One snowy April day the heroes of Gallipoli who hailed from the Antipodes invaded our Hut and made themselves at home in it at once. Taking them all round, the Anzacs were the finest-looking men I had ever seen, tall and sinewy, with clear-cut features, frank eyes, beautiful teeth and a proud gait. They were particularly easy to get on with, and extremely polite, addressing us always as "Madame" or "Lady," and invariably saluting us if we did them any little extra service. "Are you English? I've never met an English lady before, and I'd like to have a yarn with you, whenever you aren't busy," was said to all of us over and over again, or it would be: "You ladies keep us from the drink," or "I don't think I could stick this camp if it weren't for the Hut—I'd desert, as I'm not accustomed to all this discipline."

Our sympathies went out to the newcomers, partly because they were so homesick. Many

had had no letters for six or even eight months, and more than one told me that the longing for home became worse when he got news. Others complained that they found great difficulty in writing to the dear ones twelve or fourteen thousand miles away, though some appeared to cover many sheets, and used to pick a flower or a leaf from the bouquets we kept on the counter in order to enclose them. By the way, I heard that the cost of the paper and envelopes provided free by the Y.M.C.A. comes to £1,000 a week. Cards with the flags of the Allies or floral devices worked in coloured silks were bought by the hundred to send home, the men being particularly fond of those with sentimental inscriptions—"Let's have something a bit sloppy," as they expressed it.

All of us were confided in to a flattering extent. One man appealed to me to keep his money; another, alas, killed on the Somme, gave me a parcel to send to his wife; but I plumed myself most on being able to supply the address in London of the long-lost uncle of one of my new acquaintances. This was accomplished owing to the energy of a friend of mine, and I was thankful that my Anzac had not found me a broken reed.

We shopped for any soldier who needed our services, as the men were not allowed to go freely into the town. They entrusted their watches to us to be mended in an embarrassing profusion; identification discs were lost and must be replaced; members of the Public School Corps required French books and various manuals to fit themselves for their coming commissions, and a Scotch sergeant requested me to arrange French lessons for him. He fancied that he would soon grasp the language because he had discovered that "assiette" was "ashet" in Scotch, and "gigot" had the same meaning in both languages. We supplied brown paper, string, labels, needles, cottons, and so on gratis, and every now and again a man would enlist our admiration for some rather fearsome *objet d'art* that he was anxious to send to his "best girl" at the Antipodes, confidently relying on our good offices to provide a box, sealing-wax, and string.

We kept bandages and iodine at hand, and I fancy that by this simple precaution we saved many a careless man from the septic poisoning so common in the camp.

Any fatigue or discomfort that we might experience was promptly forgotten when we grasped how greatly our services were appreciated. "If you ladies knew what the whole camp thinks of you it would hurt you," was said to me on one occasion, and to all of us the remark was made, "You always serve us as if you liked doing it."

We were urged again and again not to overtire ourselves, although on Mondays there was usually disappointment expressed that we had absented ourselves on Sunday afternoons (our time off each week). I must own that I was secretly flattered when an orderly remarked to me, "On Sunday afternoons we always get such a rough lot of fellows; we have to be pretty sharp with them I can tell you." Our own experience was totally different, as throughout my stay none of us ever had a rude word or look, nor did a single soldier, be he Britisher or Anzac, ever swear in our hearing.

Every now and again, when the officials were short-handed, I was asked to take a turn at the cash-desk, and enjoyed the change of work, especially on pay-days, when the crowd seemed unending. The men stood in a long queue, never jostling one another, and amused to see me measuring off the strings of ten centime tickets with the help of notches cut in the desk. When five or seven francs' worth of tickets were demanded, it was like reeling off ribbon at a counter. The highly-paid Anzacs usually preferred twenty-franc notes, and always asked for their tickets in multiples of ten; but the British soldier never seemed to grasp the decimal coinage, and would demand twelve or six tickets out of his five-franc note. New arrivals offered English coins, and were interested to find that a shilling was worth 1 fr. 45 c.; half-a-crown, 3 fr. 55 c.; 28 fr. 55 c. being the equivalent of a pound note, though an English sovereign only realised 27 fr.

The men were fond of saying, "A meal for me and my mate," to this I would reel off ten tickets; but when it came to, "Some tobacco and matches, three fags, a cup of tea and a 'brad,'" a little mental arithmetic would be needed.

Many of the Scotch were very taciturn, and frequently pointed to the articles they wanted to buy without vouchsafing a word. I always humoured them, and business was transacted in complete silence on either side. However, once at the tobacco stall I forced a dour-looking sergeant to speak. At the time matches were extremely scarce, and in order to enable them go round we were only allowed to sell one box to each man. "Jock" pushed two tickets towards me and pointed at the matches. I gave him one box and returned

the second ticket, which he thrust vehemently at me again, and again I returned it in silence. This was too much for him, and he broke into speech, "Twa matches." "Oh, you aren't dumb after all," was my remark, and his stern face broke into a broad grin while I explained why his demand could not be granted.

At intervals the hut was visited by the concert parties organised by Miss Lena Ashwell, the talented artistes being received with such storms of enthusiasm that they said it would be hard to perform to any ordinary audience after the soldiers. The men also had their own sing-songs, the Australians producing a mesmeriser who sent us all into fits of uncontrollable laughter by the comic situations into which he put the men whom he had hypnotised.

The library was a great resource, but though the Anzacs carefully recorded their names and the titles of the books they took out, they were, alas! not nearly so punctilious in the matter of returning the volumes. Certainly some grateful spirits not only brought back missing books—in too many cases found on rubbish heaps—but presented the library with others; yet, on the whole, the arrivals from the Antipodes swept the shelves clear as if they had been visited by a swarm of locusts. Most of the men liked novels, but some were keen on serious reading, and one youth remarked, as he showed me a book of poems, "I read one of these in the morning and it hangs about me all day."

Two or three weeks after the slouch hat and the broad-brimmed round felt had invaded our hut, an epidemic of mumps and measles broke out among the Anzacs, and accordingly we were out-of-bounds to all the British troops. Until this order was repealed we had about half our usual customers, and in consequence were able to individualise the men from the Southern Cross, and make friends in a way that was impossible when business was in full swing.

Those who were ill were supposed to be confined in an isolation camp; but one day as I entered the library an Australian remarked to me cheerfully, "This place *is* a boon. I really don't know how we could get on in the isolation camp without these books!"

As I talked with man after man I began to realise that, consciously or unconsciously, they felt that the cause that had drawn them from the ends of the earth to offer their lives in its service was a holy one. Many had come with a splendid disregard of material interests. "It must have been a great wrench for you to have left your wife and children," I said to one man, and he replied, "Yes, it was; but I should never have been satisfied all the rest of my life if I hadn't come."

That seemed to be the spirit animating one and all, and my heart went out in particular to the gallant boys, several of whom had enlisted pretending that they were full-grown. One well-built youth, gently bred, had joined from school at the age of sixteen. "I used to be frightened at first when the fellows got drunk and fought in our tent," he said, "but now I only laugh," and I thought of his mother far away in New Zealand.

Another boy, like a prize-fighter in appearance and always full of mischief, returned to the hut after a spell at the Front. At my greeting his face puckered up like that of a child about to cry, and he exclaimed, "I don't want to go back to make the daisies burst up; I want to go home," and the words came from his very heart. "Of course you do, but you must see this through first!" seemed to cheer him up, and he muttered, "That's so," nodded his head approvingly, and swaggered off quite in his old style. There was a great anxiety in the eyes of another poor lad who murmured to me, "I have only just come from New Zealand and am going up the line to-morrow; I don't know how I shall behave," and I grasped that he was haunted by the fear that he might not play the man, and trust that my words were a help to him. It was hard to say good-bye when our friends left us for the Front. The Hut would be quieter on those days, so many men writing what would be their last letters, and one hated to feel that numbers would never return and that more would be maimed and broken for the rest of their lives. As an Australian remarked to me, "None of us understood what war meant until the first shipload of our wounded arrived. It was when our people saw the blinded men that they began to realise things a bit."

We had several victims of shell-shock in the hut, some mere boys with a haunted, scared look in their eyes. A splendidly-built Australian told me that he could not understand how, after nineteen months of warfare without a scratch, all his nerves should give way because some earth from a bursting shell had struck his face. But the Medical Board had declared him unfit for further service and he came to bid me good-bye. "I haven't a single bad mark against my name," he said. "Before I left home I promised my sister that I'd behave, and I've kept my word, though it's been hard not to drink sometimes when I've been with the boys." I

trust that the sea voyage and his temperate habits have restored him to health, for I always regretted that the splendid men who had come across the world viewed drunkenness with too lenient an eye. As one of them remarked to me, "We don't look upon it in the way you do; it isn't anything to keep a man awake at night about."

Another thing that struck me was the longing that one and all had to see the Mother Country. "I hope I'll get wounded badly enough to be sent to Blighty," was a wish I heard more than once. One man told me that it was necessary for a man to have friends in England, his ticket being made out to their address. This regulation, he explained, was no bar to the Anzacs, who evaded it by means of faked addresses.

"What did you think of England?" I asked an Australian who had just returned to camp after a fortnight in the Old Country. His face lit up as he answered: "It was all that I thought and a great deal more!"

The huts are only part of the work done by the Y.M.C.A. in France. We were living in a district of hospitals, and the Society looked after the relatives of wounded officers and privates, housing them and driving them to see their sick. The relatives of privates were lodged free of charge in a comfortable hostel, and those of officers could stay in a charming villa, where I never shall forget two mothers, the lives of whose sons hung in the balance from day to day, nor the stricken couple who arrived too late to say farewell to their loved one. There was tragedy round us. If we sat in the beautiful garden where cuckoos called all day and nightingales sang after dusk in the spring, our thoughts would be turned from the loveliness round us by the menacing boom of the guns at the Front some forty miles away.

The Y.M.C.A. also brought much comfort to the relatives of the dead by means of photography. One of their helpers made it his special task to photograph the graves of fallen soldiers. I visited one cemetery among the sand-dunes and the pines, the French having given half the ground to our heroic dead, reserving the rest for their own men.

Our soldiers lie in long rows, each mound marked by a simple wooden cross, on which hangs a moss wreath set with flowers, and one felt that this God's Acre was a specially sacred spot. The gallant company who lay there, cut off in their prime, had offered themselves willingly for a great cause, and had, indeed, been "faithful unto death."

"Snapshots from Home" was another scheme by which the men at the Front, whether from Great Britain or the Dominions, could be cheered by the arrival of portraits of their families taken by willing helpers. An Australian who heard of this told me that he had just received the joyful news that he was a father, and he hastened to fill in the form that would procure him a picture of his baby-boy.

The Y.M.C.A. also undertook the task of meeting night and early morning trains full of tired men bound "up the line," who were thankful for a hot drink and a smoke.

Three of us took part in this work on one occasion in order to have the experience. We had to be at the Y.M.C.A. headquarters by 3 a.m., where we found a big car loaded up with urns of tea and cocoa and a case of biscuits, and we followed in its wake to the railway siding. Here a train full of reinforcements pulled up, and we did a brisk trade with exhausted Tommies who had been travelling all night. chattering with them in the intervals of filling their billies and mugs. The men rushed up for tea until the last moment, making us fear that they might be left behind, and as the train started we distributed chocolate and cigarettes, bidding our brave defenders good luck as they went off to their unknown fate.

Three happy months slipped by all too fast, and I left the Hut with deep regret. I often wonder how my friends have fared. In my mind's eye I can see one, a born soldier, who had served under the banner of Italy during the Tripoli campaign, and who knew Constantinople well. We always exchanged greetings in Italian when we met at the counter, and he told me many interesting things.

Then there was the white-haired man, erect and sinewy, who had been one of the earliest leaders in the campaign that ended in the complete triumph of the Labour Party in Australia. He had known Hughes when the eloquent Prime Minister was poor and obscure, and he took much trouble in explaining to me the state of politics under the Southern Cross.

I must not forget John and Alf, our cheery and willing boy orderlies from Birmingham, who had enlisted at the tender age of sixteen. "We couldn't stand the posters, and as lots of grown-up men wouldn't do their 'bit' we just had to enlist." Thus John explained to me one day, and added that when his widowed mother, whose only child he was, heard the news, she took to her bed for a fortnight! Another of our orderlies, a Britisher, had had a chequered

career. He had worked as a cowboy in the States, and had got a lucrative post in Mexico when he was captured by Villa's forces and cast into prison. "They only gave me food when they felt like it," was his comment on his imprisonment, and finally he was brought down to the coast in chains. On the outbreak of war he took ship to Tasmania and enlisted under the Australian flag, going through the Gallipoli campaign without a scratch.

These are but a few glimpses of a great and splendid company—men who at the call of duty went to meet death with "proud, unreluctant feet"—one and all offering up their lives without compulsion in the sacred cause of Justice and Freedom. Over and over again I felt what a privilege was mine to be able to serve in ever so small a degree the very flower of the race to which I have always been so proud to belong, and I realised more keenly than before how immense was our debt to the manhood of the Empire and how impossible of repayment.

DISCUSSION.

THE CHAIRMAN (Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.), in opening the discussion, said it was a peculiar pleasure to hear at first hand such an interesting and amusing account of the actual working of the Y.M.C.A. huts in France, and the social conditions under which the workers laboured. Some people might ask what the Y.M.C.A. huts had to do with the Royal Society of Arts, whose interests were avowedly in the direction of Arts, Manufactures, and Commerce. Independent of the fact that at present everything which concerned the welfare of our soldiers at the Front ought to concern the Society, there was another side to the question. The Society prided itself on being by no means a negligible factor in the educational schemes of the country; and the work of the Y.M.C.A. had its educational side. Judging from what Miss Sykes had said, there were two principal things which the soldiers learned in the huts, the first being Christianity and the second good manners. He did not suggest for an instant that as a rule our soldiers went out to the Front without at any rate the rudiments of knowledge of how they should behave socially. As Miss Sykes had stated, there must be very many gentlemen among them, and there were some points on which British soldiers could give a lesson to those of other countries. A story appeared in one of the newspapers a short time ago of a German soldier who was dragged out of his trench covered with mud, cold, wet, shivering and hungry, and who was brought to one of the huts. What he expected to get when he fell into the hands of the English he (the Chairman) did not know, but what he did get when he reached the hut was a cup of hot coffee, and he then said with a smile, and in perfectly good English, "This is the spirit of the English." He could not vouch for the truth of the story, but all present could vouch for the sentiment which the German prisoner expressed. The sentiment of chivalry towards a beaten foe had existed amongst British soldiers through all the centuries. It had come down as a hereditary asset to them from the days when Edward the Black Prince entertained King John of France, on the field of battle, after having well beaten him at Poitiers, and probably it extended even farther back than that. But a man learned more than that when he joined the Army. As a general rule, men after being put through a certain period of training were enormously improved physically, and in every way they were much more of men than they were before. They also acquired a certain mental equipment; their outlook on things in general was broadened, and they had altogether a better appreciation of the social conditions of the world than they had before. Ian Hay narrated a story of one of his smartest sergeants who, when he joined, was a Socialist, and whose first idea was to organise so far as he could a small trades union in his own company—not for the purpose of raising a strike against military orders, but for securing a fund which would go towards paying the fines of himself and his comrades for disregarding any duty imposed upon them. He found that it did not altogether answer, and when he further discovered that the money that was deducted from his pay on account of his own faults did not go into the pockets of the officers of the company but really went to the King, his view of the whole situation entirely changed. The Army was perhaps the greatest democratic institution in the country; in it men of all sorts met and rubbed shoulders together and learned things from each other, and by degrees they acquired, at any rate to a certain extent on all things that really mattered, something of the same opinion. He could not help thinking that, with the assistance of the huts, which brought all the men together, and promoted social communion between them, there was a very powerful educational factor at work in France, and it would be a thousand pities if the great work which was now being carried on there was to fail hereafter—if some of that educational process did not "stick." When the men came home and were distributed by hundreds of thousands over the country it would be a very great surprise to him if they did not leaven the whole lump in England, and produce something like a social revolution which had nothing to do with the Socialists. But it was clear that if hopes in that direction were to be fulfilled the work of the Y.M.C.A. in France should continue steadily at home in this country when the war was over, and that, he understood, was exactly what the Y.M.C.A. desired to bring about. They had

already taken the matter in hand, and had erected huts in different places all over the country, including twenty-five in London. He had heard it said that the Y.M.C.A. hut system would find itself up against the publicans and the public-houses. Personally, he did not think that would prove to be so. He had a strong conviction that publicans were as good and as sound a body in the British Constitution as any other community; they did not want men to misuse or abuse their hospitality, but they naturally wanted to make the best of their trade, and in order to do so they did all they could to make it attractive. The Y.M.C.A. must do the same, and to that end they must not drop the system which they had adopted in France. It was to be hoped that, when the work of the Y.M.C.A. was in full swing in this country to an extent which had hitherto not been the case, the ladies of the country who could bring such an influence to bear on the manners of men would not hold back because the war was over, but would still take the same interest in the work of the huts—not at all in the position of barmaids, but by using their influence to make the huts a home for the men. If the ladies who were kind enough to undertake the work were gifted with the graces of sympathy and of wisdom possessed by Miss Sykes he had the greatest hopes for the future.

The Secretary read the following letter from Dr. J. Holland Rose, University Reader in Modern History at Cambridge :—I wish to emphasise the need which already exists for more workers, always provided that they are capable, tactful, and in other respects suitable. I believe that even now it is not fully realised how great is the need for additional workers. My experience at the large base-camps, and my talks with those who recently came from them, confirm my impression as to the growing strain on the helpers out there. The new military regulations, imposing the term of four months' service, and compelling the wearing of uniform both by women and men, will probably hinder a certain number from going out. And if many intending workers are thus hindered there may be a serious crisis, which will render it difficult to carry on the work efficiently at the ever-increasing number of huts. For myself, I believe that this crisis will soon be upon us; and it is well that that prospect should be faced in time by those on whom lies the responsibility for keeping up an adequate supply of workers in France.

Mr. E. T. Scammell said the suggestions made by the Chairman in regard to the work of the Y.M.C.A. at home in the future were very wise and opportune. Last Christmas an effort was made by the Y.M.C.A. to obtain hospitality in the homes of the people of the country for any soldiers on leave from the Front. Hundreds of invitations were received from people in London anxious to entertain men during Christmas time, but the effort was not a complete success owing to a much smaller number of men receiving leave than had been anticipated. A fresh effort was now being made with the object of providing hospitality in the homes of the people for convalescents from the hospitals, and the Y.M.C.A. required ladies of organising ability and sufficient leisure to organise a movement of the kind.

On the motion of the Chairman a hearty vote of thanks was accorded to Miss Sykes for her very interesting paper, and the meeting terminated.

PHEASANT FARMS IN SOUTH CHINA.

In a recent report the United States Consul-General at Hong-Kong states that the raising of domesticated pheasants is upon a very large scale, particularly in certain districts near Yunnanfu, Yunnan Province. Direct shipments to the United States are on the increase, and inquiries indicate that the trade with America will increase even more rapidly.

At present the pheasant feathers and skins reaching Hong-Kong come almost entirely from the farms near Yunnanfu. There are twelve of these farms of some importance, one of them raising well toward 200,000 birds a year, while the total output is estimated to be in excess of 300,000, and may be much larger. The farming includes both the golden and the silver pheasants. The golden are the more common birds, but there is comparatively little difference in the demand for the two varieties.

The birds are raised much as are ordinary fowls, the eggs being hatched in Chinese incubators and the chicks handled in native-made brooders on the larger farms, though the rule on the smaller farms seems to be to rely upon the hens for hatching. The birds are usually worth at Yunnanfu from $1 to $1.20 silver currency (from $0.40 to $0.50 gold) each. Of this value about half represents the value of the skins and feathers for export, and the rest the value of the meat of the birds. Most of the birds are killed about the Chinese New Year, and are used for food during the festival season, though there is a good demand for them at all times.

There is practically no distinction made in the price of the male and female birds as a rule. Before the war the business of shipping the feathers of these birds out of Yunnan to Hong-Kong and thence to Europe was largely in the control of German firms. Since the war the business has been taken up mostly by French and Danish firms. The immensely larger portion of the output of the farms goes to Europe, Marseilles still being the chief centre of the trade in Europe, the understanding being that many of the birds are there prepared for re-export to the United States, and particularly South America. The skins and feathers are seldom used locally by the Chinese, though a few are employed now and then in Chinese theatrical costumes.

The skins are cured simply by immersing in a solution of carbolic acid for disinfection, by treatment with an alum preparation, and steaming and then drying. They come to Hong-Kong usually in small bales protected by matting, but the more valuable feathers and skins are separately wrapped in paper and packed in cases. They are usually exported from Hong-Kong in cases.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Cotton Substitutes.—It can be foreseen that the general public will soon be wearing and using more cotton goods. The severer restrictions upon the disposal of wool and flax ensure that cotton will have to be taken instead, and the compulsion will not be universally welcome. In the eyes of a good many householders cotton is admirable in its own allotted sphere, but outside of a definite range of purposes is looked on as a trespasser. The prejudice is intelligible, for, great and powerful as cotton has become, it is still somewhat of an upstart in the Western world. Its position has been gained by elbowing others aside by dint of superior cheapness. Silk, linen or wool goods may be cheaper for containing cotton, but they are not inevitably better, and cotton has incurred some of the odium in which substitutes and adulterants are commonly held. Hence, no doubt, some of the disposition to avoid calling cotton goods by the plain name "cotton," and to give them names which more or less shroud their identity. It is not to be doubted that "velveteen" is a better trade name than cotton velvet, although at some date it must have been exposed to the same objection as "flannelette." No objection can be made to fancy names which raise no suggestion of false composition, and these should increase in view of the growing disposition of manufacturers to identify themselves with their product.

Merits and Demerits.—Cottons are open to some rational as well as unreasoning objections, for no one textile embodies all the virtues. Cotton is a better heat conductor than wool, although that disadvantage is remediable in part by raising a fine fur of fibre upon the surface to check conduction and retain a layer of dry air. It is less strong than flax, and no means of making short-fibred cotton as strong as long-fibred linen are likely to be found. It is more inflammable than the animal fibres, and although means of fireproofing cotton are not unknown, the expense of treatment is material and its effects are not final. Cotton absorbs moisture freely and when wet is cold to the touch; but it can be converted at need into respectably efficient macintoshes and raincoats. Cottons can be made as lustrous as need be for those who want sheen, and no fibre is capable of so many mutations. In wear it soils more quickly than wool or silk and in general its colours are not so permanent, although this rule is not absolute. In their degree all these characteristics influence the sale and popularity of cotton goods in substitution for other articles; but perhaps the most effective commercial improvement which could be introduced would be one to prevent cotton cloths from creasing. A fabric that could regain its straightness after folding in the same way as silks and wool goods do would make fortunes for its producers. Under ordinary conditions, cottons are shut out from an immense additional consumption for no more substantial reason than that they look tumbled too soon in wear.

Consumption of Cotton.—It cannot be affirmed of a certainty that an increased substitution of cotton for linen and wool will increase the world's consumption of raw cotton within a given year. The flax and wool crops are small things beside the 12,000,000,000 lb. or so of raw cotton now annually produced, and cotton is consumed preponderantly by races which barely know an alternative material. Every new employment helps to dispose of more cotton; but a consumption which grows at the average rate of 500,000,000 lb. a year is capable of accommodating many fluctuations of demand. Highly important British manufacturers have well before their eyes the desirability of cultivating a winter trade in relatively heavy and warm cotton cloths, and their efforts should have a chance of fruition this year. The progress already made in adapting cotton to new uses does but make it more certain that there remain possibilities still unexplored, and these may form the subject of unlimited research work.

Neglected Business.—The Continentals in the past have done much more weaving upon single worsted warps than have British manufacturers, whose warps are usually of two-fold thread. The single warp makes a more lissome cloth, draping rather more elegantly, but somewhat more difficult to weave. The single yarn calls for more preparation than two-fold to enable it to withstand the chafing of the loom, and with fair unanimity British manufacturers have fought shy of the business. In a discussion of the technical aspects of the problem before the Bradford Textile Society a spinner remarked that no sooner did he begin to think of making single-warp yarn for weaving than he was confronted with the superior attractions of orders from the hosiery trade. To both spinners of yarn and weavers of cloth the trade has appeared as second-best business. The comparison is conditioned, of course, by the price obtainable in competition with the Continentals, and more

speakers than one agreed that this particular class of trade could be captured. One line proposed was the evolution of single-warp cloths showing some distinct difference from the Continental type—a development which cannot be dismissed as impossible. It has, however, to be borne in mind that Labour asserts a voice in all such matters, and that it is not precisely as easy to get weavers for work on sized and relatively frail warps as for the stouter two-folds. Thus wages, which are already higher than the Continental scale, would presumably have to be increased.

Trade Restrictions.—The suggestions offered by the National Service Department to retailers as to their trading relations with the public have not been too favourably received in drapery circles. They may be taken, no doubt, to reflect the official desire to curtail non-essential expenditure, and conceivably they will have some such effect. The pious warnings against extravagance in dress issued a year ago produced a temporary check perceptible at the drapery counters, but the caution has long vanished into limbo. Manufacturers have shown no reluctance to reduce the credits granted by them, and an important curtailment of the credit given to wholesalers for tailoring cloths has been effected by English, Scottish and Irish woollen and worsted manufacturers. In the promiscuous rush for goods producers have been able to evade those who have asked for long credit, and to tighten trading terms all round. The natural inclination to reduce risks has been hastened by a cost of materials which has doubled or trebled the amount required to carry normal stocks. Retailers cannot be quite insensitive to the same influences, and it may be believed that the paternal official suggestions will not prove the greatest obstacle to their further trading. Absence of goods to sell will be a more radical deterrent than absence of window-show or credit payments, and drapers can by no means count on obtaining the same kinds and quantities as hitherto. Wool and flax materials, at any rate, will not be released with the accustomed freedom for the purposes of home trade, and engagement on Government contracts or export orders is becoming indispensable to existence as a manufacturer.

Sumptuary Laws.—The principle in modern sumptuary regulation is that of striking at the source of import or of manufacture, and it was presumably not in order to facilitate administration that our forefathers laid restriction upon the individual wearer. Possession of £100 a year formed a franchise under the Act of 1337 forbidding the wear of anything but English cloth. Under the Scottish statute of 1471 "the gret pow'te of the Realme" was cited as the reason for forbidding "silks in gown doublate or cloks except knychts mestrallis and herralds," and to those who "may spend a hwndretht punds wortht of lands rent." Velvet hats and caps were forbidden in 1566 to any man "under the Degree of a Knight or of a Lordes soone." It is not clear that the motive of these ordinances was invariably national economy, and they need not be pursued beyond the Scots law of 1621 preventing servants from wearing clothes other than cloths, fustians, canvas or stuffs of the national manufacture. At a time when furriers are currently supposed to have done better than ever, a petition of the Mystery of Skinners of London to Elizabeth may be noticed. The handicraftsmen maintained that the usual wearing of furs in 1590 was "utterly neglected and eaten out by the too ordinary, lavish and unnecessary use of velvets and silks," which rival articles were said to be "drinking up the wealth of the realm."

Japanese Silks.—Customers for Japanese silks have had to bear with so much irregularity in the quality of supplies that the news of the opening of a new Conditioning House in Yokohama should be welcome. Warehouses and a finishing works for imparting a standard finish to the cloths are being built. It is well understood that irregularities of quality are to be expected in goods made and finished by a multitude of small producers, and it is acknowledged that foreign buyers have tempted the small man to adopt deceitful courses. Something may be hoped from measures which give the trade an approach to the uniformity that is more readily secured under large-scale factory conditions. Inspection has not shown itself a sovereign cure in the past, and it will be interesting to see whether the new standards are proof against deterioration. The plain uncoloured silks of Japan stand in extraordinarily little danger from direct competition, and better prices could be realised by saving the buyer any doubts of the quality to be received.

OBITUARY.

The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.—Lord Cromer died at his residence in Wimpole Street on January 29th. The son of Mr. Henry Baring, M.P., he was born at Cromer Hall, Norfolk, in 1841. At the age of fourteen he entered the Royal Military Academy at Woolwich. As he himself stated at a meeting of the Royal Society of Arts, he was at first rejected for short sight, but pressure was brought to bear on the authorities and "the matter was reconsidered." In 1858 he entered the Royal Artillery. Three years later he went to the Ionian Islands as A.D.C. to Sir Henry Storks, and in 1865 he acted as Secretary to the Commission sent to Jamaica

to inquire into the outbreak of the coloured population and the repressive measures adopted by Governor Eyre. In 1872 he went to India as private secretary to the Viceroy, Lord Northbrook, where he had ample opportunities, during the terrible famine of 1874, of studying some of the economic problems of the great Dependency.

In 1877 Major Baring was sent to Cairo as Commissioner of the Egyptian Public Debt, and in 1879 he was appointed Controller-General in Egypt. The following year he returned to India as Financial Member of the Council of the Governor-General. In 1883 he was recalled to Egypt as H.M. Agent and Consul-General, a post which he held for twenty-four years.

Lord Cromer's work in Egypt, which won for him the reputation of one of the greatest Empire builders in British history, is too well known to call for more than a mere summary here. Under the malign misgovernment of Ismail, this naturally rich and fertile country had sunk to "the *nadir* of financial chaos and popular misery." In the course of his rule Lord Cromer reduced the public debt (which had sprung from seven to a hundred millions sterling in a dozen years), practically abolished forced labour, eased the land-tax by one-third, cleansed the Courts, and established institutions capable of supplying competent men for the judiciary and the Government service.

Lord Cromer was elected a member of the Royal Society of Arts in 1903. In 1908 he received the Society's Albert Medal "in recognition of his pre-eminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and by the initiation of great works has opened up new fields for enterprise." In the same year he took the chair at the meeting when Sir Hanbury Brown, K.C.M.G., read a paper on "Irrigation in Egypt under British Direction," and in 1911 he again presided when Mr. P. J. Hartog read a paper on "Examinations in their bearing on National Efficiency." He served on the Council as Vice-President from 1908 to 1912.

GENERAL NOTES.

BANK MEETINGS.—Sir Edward Holden, Chairman of the London City and Midland Bank, Limited, in the course of his address to the shareholders on January 26th, described the constitution of the Reichsbank, the institution in which the whole German financial system is centralised and which acts as the Central Bank for most of the great Joint Stock Banks of Germany. The direction of the bank was actually under the control of the Kaiser through his Minister Herr von Bethmann-Hollweg. In addition to its function as the Bank of Issue for the Government, the Reichsbank carried on an ordinary banking business. In times of peace its notes were secured according to law by gold bullion or coin, Imperial Treasury notes, and current German money to the extent of one-third of the notes in circulation, but since the war, by the law of August 4th, 1914, they had added another form of cover, viz., the notes of the Darlohnskassen, *i.e.* of the small loan banks which had been established in different parts of the Empire, and at which advances on all kinds of securities might be obtained. The custom of the Reichsbank, however, had always been to maintain a minimum of 33⅓ per cent. in gold only against its notes in circulation. When the war began in July, 1914, the amount of such notes in circulation was about 94 millions sterling, and by the end of December, 1916, they had reached a total of 403 millions. The gold held by the Reichsbank on July 23rd, 1914, was 68 millions, being a percentage of 71·7 of the notes in circulation, and by the end of December, 1916, the gold amounted to 126 millions and the percentage had fallen to 31·3. During the progress of the war the Reichsbank authorities had foreseen that there would be a tremendous increase in their note circulation, and that it would be absolutely necessary for them to put forth extraordinary efforts gradually to increase their gold as the note issue increased. Travellers had been stopped at the frontiers and their gold taken from them in exchange for notes. The clergy had preached from the pulpits urging the people to give up their gold and take notes. Gold ornaments had been melted down and the metal sent into the Reichsbank in exchange for notes. The soldiers had been given certain privileges in exchange for any gold which they could collect. More recently the holders of hoarded coins were threatened that the gold in the possession of the bank would be recoined and the design changed, and that their hoarded pieces would no longer be regarded as currency.—Mr. Walter Leaf, presiding at the annual general meeting of the London County and Westminster Bank, Limited, dealt, among other subjects, with the schemes for mobilising of securities. The two conspicuous and highly successful operations of the past year had been the mobilisation of securities by way of sale or loan to the Government, and the system of continuous day to day loans by means of short-term borrowing on Treasury Bills. The former operation was designed to deal with the foreign exchanges, and more particularly American. The New York rate had been a subject of much anxiety to all, and particularly to the small committee of experts who had had the great responsibility of dealing with it. The second outstanding feature in our national finance at the end of the year was the enormous amount of indebtedness at short date—over £1,100,000,000 in Treasury Bills with not more than twelve months to run. In addition to this there were many hundreds of millions in Exchequer Bonds, in War Certificates, in loans to the United States, and in Currency Notes. It was clear to all that the time had come

when we should undertake a great operation both for the funding of our short-term indebtedness and at the same time make a fresh loan on the largest possible scale. The system of day to day borrowing had proved marvellously successful in providing the necessary money, but it had now reached a point at which a halt must be called, the position strengthened, and a strong call made to the nation for a great loan.

Royal National Life-boat Institution.—The number of lives saved by the life-boats in 1916 was 1,185. This constitutes a record for the whole period of ninety-three years since the Institution was established, and there has seldom, if ever, been concentrated within three days of life-boat work a more splendid series of achievements than those of the Deal, Kingsdown, Ramsgate, Tynemouth, and Holy Island life-boats, which resulted in the rescue of 230 lives between November 19th and 21st. The life-boats have also rescued over 750 sailors, soldiers, doctors, nurses, and others from H.M. ships and other vessels which have been mined, torpedoed, or otherwise in jeopardy from causes arising directly out of the war. Unfortunately twenty-one life-boatmen have perished since the outbreak of war, and three splendid life-boats and several others have been severely damaged since August, 1914. At the same time the income of the Institution was £21,000 less in 1916 than in the previous year. The Institution is urgently in need of funds to enable it to carry on its work which has been the means of saving no fewer than 54,600 lives.

American Gift for Belgian Relief.—Fellows of the Society who read Mr. W. A. M. Goode's paper on "Relief Work in Belgium," published in the last number of the *Journal*, will be interested in a message from the Exchange Telegraph Company, published in the *Times* of January 31st. From this it appears that in response to an appeal by Mr. Herbert C. Hoover, Chairman of the American Commission for Relief in Belgium, 500 members of the Rocky Mountain Club, of New York, composed of the principal mining men of the Far West, have decided to forego the building of a club house, and hand over £200,000 —the estimated cost of the building—to Mr. Hoover for the purposes of Belgian relief.

Wine for French Soldiers.—According to the official returns, in 1915 the French Government requisitioned and purchased 4,685,000 hectolitres, or more than six hundred and eighteen million large bottles of claret or red wine, for the use of its armies. Each officer and man daily receives half a litre of wine, and the actual number of bottles requisitioned in the year mentioned was 927,630,000 half litres. During the following twelve months of 1916, when the forces engaged in the different theatres of operation had been largely increased, the total quantity of wine requisitioned by the Government of the Republic is estimated at 6,000,000 hectolitres, representing one thousand one hundred and eighty-eight million half litres (792,000,000 large bottles).

MEETINGS OF THE SOCIETY

(Up to Easter).

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

February 7.—Robert Fortescue Fox, M.D., "The Future of British Spas." Sir Thomas Barlow, Bt., K.C.V.O., M.D., LL.D., F.R.C.P., F.R.S., will preside.

February 14.—Lawrence Chubb, Secretary to the Commons and Footpaths Preservation Society, "Highways and Byways." The Right Hon. Lord Farrer will preside.

February 21.—Mrs. C. Hoster, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment." Lady Emmott will preside.

February 28.—Francis A. Hocking, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs."

March 7.—James Harris Vickery, LL.B., "German Business Methods."

March 14.—Dr. J. Augustus Voelcker, "Fertilisers and their Supply in War Time."

March 21.—G. W. Jones, "Colour Printing and some Recent Developments." Carmichael Thomas, Chairman of the *Graphic* and *Daily Graphic*, will preside.

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

February 15. — Professor H. Maxwell-Lefroy, M.A., F.E.S., F.Z.S., Imperial College of Science and Technology, "The Indian Silk Industry." The Right Hon. Lord Islington, P.C., G.C.M G., D.S.O., Under-Secretary of State for India, will preside.

March 15.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

February 27. — Alfred Bigland, M.P., "Imperial Assets and how to use them."

March 27.—The Hon. Frederick W. Young, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

Syllabus.

LECTURE II.—FEBRUARY 5.—*Mediæval and Renaissance Periods.* Republics and Duchy towns of Italy—Florence, Venice, Milan, Rome. Free cities of the Empire—Nuremberg, Ghent, Ypres, Bruges, Antwerp, and Brussels. France and Germany. English types.

LECTURE III.—FEBRUARY 12.—*The Nineteenth Century.* Paris under the Empire. Vienna—Ringstrasse and buildings. Berlin—Centre and growth. Washington, New York, and Chicago. England—Late Georgian and Victorian progress.

LECTURE IV.—FEBRUARY 19.—*The Housing and Town Planning Act*, 1909. Problems for solution. Procedure. Advice to promoters. Preparation of schemes. Architectural considerations. Examples of Garden City movements—Letchworth, Hampstead, etc. The problem of London.

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m. :—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 5, 12, 19.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 5 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor A. Beresford Pite, "The History and Practice of Town Planning and Civic Architecture." (Lecture II.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. S. M. Zwemer, "Islam and Animism."

Royal Institution, Albemarle-street, W., 5 p.m General Monthly Meeting.

Geographical Society. Burlington-gardens, W., 5.30 p.m. Dr. J. Scott Keltie, "Thirty Years' Work of the Royal Geographical Society."

Electrical Engineers, Institution of (Western Local Section), Merchant Venturers' Technical College, Bristol, 5 p.m. Mr. J. S. Peek, "The Parallel Operation of Electrical Power Stations."

TUESDAY, FEBRUARY 6 ... Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Dr. G. de Swietochowski, "The Future of Poland."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Old Brain and the New Brain, and their Meaning." (Lecture IV.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. G. W. Humphreys, "The Main Drainage System of London."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. S. Gardner, "English Gothic Foliage Sculpture."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. L. A. Borradaile, "On the Structure and Functions of the Mouth-parts of the Palæmonid Prawns." 2. Dr. F. E. Beddard, "On the Scolex in the Cestode Genus *Duthiersia*, and on the Species of that Genus." 3. Professor H. G. Plimmer, "Report on the Deaths which occurred in the Zoological Gardens during 1916."

Röentgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. Dr. E. E. Fournier D'Albe, "Some Properties and Applications of Selenium."

WEDNESDAY, FEBRUARY 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. R. Fortescue Fox, "The Future of British Spas."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Lady Barrett, M.D., "The Rôle of the Midwife and the Protection of Motherhood."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Annual Meeting. 2. Messrs. J. E. Marsh and C. G. Lye, "The Quantitative Estimation of Mercury in Organic Compounds." 3. Mr. G. D. Elsdon, "The Shrewsbury and Knapp Process for the Detection of Coconut Oil." 4. Mr. W. Partridge, "The Detection of Rose Petals in Blue Pill."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. G. B. Grundy, "The Evidence of the Anglo-Saxon Charters on the Road System of England."

School of Oriental Studies, London Institution, Finsbury-circus, E.C., 5 p.m. Mr. C. O. Blagden, "Malay."

THURSDAY, FEBRUARY 8...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. G. Donnan, "The Mechanism of Chemical Change." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. A. L. Coburn, "Vortography and its relations to Modern Art."

Optical Society, at the Chemical Society, Burlington House, W., 7.30 p.m. 1. Annual Meeting. 2. Mr. J. W. French, "More Notes on Glass Grinding and Polishing."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. R. Townend, "Frequency Changers."

FRIDAY, FEBRUARY 9...National Land and Home League, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 10.30 a.m. Conference.

Economics and Political Science, London School of, Clare Market, W.C., 5 p.m Mr. O. C. Beale, "Metals as the Base of Imperial Strength."

Royal Institution, Albemarle-street, W., 9 p.m. Mr. D. Jones, "Experimental Phonetics and its Utility to the Linguist."

Malacological Society, Burlington House, W., 7 p.m. Annual Meeting. Presidential Address: "Systematic List of the *Marginellidæ*."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture IV.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. Annual General Meeting.

SATURDAY, FEBRUARY 10...National Land and Home League, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 10.30 a.m. Conference continued.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. H. W. Davies, "Colour from Diaphony to Debussy." (Lecture II.)

BANKING SUPPLEMENT.

THE LONDON CITY & MIDLAND BANK

ESTABLISHED 1836. **LIMITED.**

Subscribed Capital, £22,947,804. Paid-up Capital, £4,780,792 10s.
Reserve Fund, £4,000,000.

DIRECTORS.

Sir EDWARD H. HOLDEN, Bart., *Chairman and Managing Director.*
WILLIAM GRAHAM BRADSHAW, Esq., London, *Deputy-Chairman.*

Report of the Auditors to the Shareholders of the London City & Midland Bank, Limited.

In accordance with the provisions of Sub-section 2 of Section 113 of the Companies (Consolidation) Act, 1908, we report as follows:—

We have examined the above Balance Sheet in detail with the Books at Head Office and with the certified Returns from the Branches. We have satisfied ourselves as to the correctness of the Cash Balances and the Bills of Exchange and have verified the correctness of the Money at Call and Short Notice. We have also verified the Securities representing the Investments of the Bank, and having obtained all the information and explanations we have required, we are of opinion that such Balance Sheet is properly drawn up so as to exhibit a true and correct view of the state of the Company's affairs according to the best of our information and the explanations given to us and as shown by the books of the Company.

No. 3,351. VOL. LXV.

FRIDAY, FEBRUARY 9, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 12th, at 4.30 p.m. (Cantor Lecture.) PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." (Lecture III.)

WEDNESDAY, FEBRUARY 14th, at 4.30 p.m. (Ordinary Meeting.) LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Byways." The RIGHT HON. LORD FARRER will preside.

THURSDAY, FEBRUARY 15th, at 4.30 p.m. (Indian Section.) PROFESSOR H. MAXWELL-LEFROY, M.A., F.E.S., F.Z.S., Imperial College of Science and Technology, "The Indian Silk Industry." The RIGHT HON. LORD ISLINGTON, P.C., G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, February 5th, PROFESSOR A. BERESFORD PITE, F.R.I.B.A., delivered the second lecture of his course on "Town Planning and Civic Architecture."

The lectures will be published in the *Journal* during the summer recess.

HOWARD LECTURES.

Professor William Ripper, D.Eng., D.Sc., having been appointed Vice-Chancellor of the University of Sheffield in place of Mr. H. A. L. Fisher, who has now become Minister of Education, will be unable to deliver the course of Howard Lectures on "Works Organisation and Efficiency" which have been announced in the *Journal* for April 23rd and 30th and May 7th. He will, however, read a paper on this subject at one of the Ordinary Meetings after Easter.

A course of two Howard Lectures will be delivered by Mr. William George Fearnsides, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, on "The National Shortage of Cheap Iron Ore Supplies" on Mondays, April 30th and May 7th, at 4 p.m. The lectures will deal with (1) "Available Home Supplies of Iron Ore"; and (2) "Overseas Iron Fields which Supply the British Market."

PROCEEDINGS OF THE SOCIETY.

NINTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 7th, 1917; SIR THOMAS BARLOW, Bt., K.C.V.O., M.D., F.R.C.P., LL.D., F.R.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Beaumont, Ivor, A.R.C.A., F.I.B.D., 74, Addison-way, Hampstead Garden Suburb, N.W.

Bebianno, Affonso, 858, Rua Barão de Mesquito, Rio de Janeiro, Brazil, South America.

Gaunt, Edgar Lawson, "Nethway," Horsforth, near Leeds.

Jones, George W., Gough-square, E.C.

Mervyn-Howell, William, 13, Cathedral-road, Cardiff; and 8, Essex-court, Temple, E.C.

Starr, David Alfred, Clyde Valley Electrical Power Company, 53, Bothwell-street, Glasgow.

The following candidates were balloted for and duly elected Fellows of the Society:—

Beale, Lieut.-Colonel W., c/o Thomas Cook and Son, Ludgate-circus, E.C.

Blades, Alfred, Messrs. Blades, East and Blades, 23, Abchurch-lane, E.C.

Burnett-Hurst, Professor Alexander Robert, Sydenham College of Commerce and Economics, University of Bombay, Bombay, India.

Dreer, William F., 2121, Garden-street, Santa Barbara, California, U.S.A.

Hazard, Frederick Rowland, Syracuse, New York, U.S.A.

Islington, The Right Hon. Lord, P.C., G.C.M.G., D.S.O., 8, Chesterfield-gardens, W.

Krishna, Siri, M.A., Ludhiana Ice Factory, Ludhiana, Punjab, India.

Kumar, Hukm Chand, B.A., D.A.V., High School, Quetta, Baluchistan, India.

McCrone, Robert, Haughbank House, Mauchline, Ayrshire, N.B.

Mackenzie, Lady Owen, 6, Chesham-street, S.W.

Ong Boon Tat, 29, South Canal-road, Singapore, Straits Settlements.

Reid, Sir Marshall Frederick, C.I.E., Woodcote Lodge, Epsom, Surrey.

Ring, John, 508, Merchants' Exchange, St. Louis, Missouri, U S.A.

Schuster, Professor Arthur, D.Sc., F.R.S., Yeldall, Twyford, Berks.

Sethi, Seth Mauekchand B. (Tazr-ul-Mulk), Gwalior, India.

Sheppard, William Didsbury, C.I.E., East India United Service Club, 16, St. James's-square, S.W.

Tabor, Frederick Richard, 3, Duke-street, Adelphi, W.C.

Tilston, Henry Edward, M.I.N.A., Calle Cangallo 499, Buenos Aires, Argentina, South America.

Waterlow, Edgar L., M.A., Messrs. Waterlow and Sons, Ltd., Great Winchester-street, E.C.

Wigglesworth, Edwin, 9, Carlton Mansions, Holland Park-gardens, W.

The paper read was—

THE FUTURE OF BRITISH SPAS.

By ROBERT FORTESCUE FOX, M.D.(Lond.), F.R.Met.S.

When more than two hundred years ago, and again a century later, Europe was ravaged by war, as it is now, the English spas were at the height of their prosperity. The memoirs of those times furnish an entertaining picture of Bath or Tunbridge Wells or Cheltenham thronged by the fashiona le world. Those who came for health and healthful recreation mingled with the gay throng who cared only for notor ety or display, and with others whose object it was to prick their jaded appetite for pleasure by a round of excitements and dissipations in a new scene. We may read of coaches and six taking the road for the waters, of beaux and belles alike disporting themselves in laces and satins, and carried in chairs to their rendezvous at the springs; and of celebrated beauties holding court whilst they completed their toilet or elegantly drank the morning draught. It would scarcely be just to hold the spas in any country responsible for the extravagances of manners that they witnessed. It was the custom in those times for the *beau monde* to gather at one or another of the English spas, just as later on in the Victorian age British invalids and health seekers in a more serious spirit resorted to the waters of Germany and France.

A great gulf is fixed between those earlier days and these. Men and manners have changed, but the waters go on. Another great European war has brought the British spas once more into the public eye, and this time not for fashion or idle display, but for the care and restoration of wounded men.

I propose in this paper first of all to ask your attention to some outstanding characters of the chief British spas. They do not form a large group in comparison with the spas of some other countries, but it should be possible now to indicate rather more definitely than heretofore the place which they hold, or should hold, amongst the health resorts of Europe. In this connection I shall notice some valuable British springs that appear to me to have been neglected.

Secondly, with your permission, I should like to place on record what has been accomplished during the past two years by means of waters and baths in this country for the treatment of soldiers.

Lastly, I propose to touch upon the new science which underlies and substantiates all treatment by means of waters and baths. I shall ask you to consider by what means this new branch of science can best be promoted.

A cursory review of the Br tish spas shows that several important types of medicinal water are represented in our country. First and foremost are the thermal waters, which flow from a considerable depth in the rocks, and have chemical and physical properties quite unlike other waters. The origin of these waters is a fascinating study. According to one theory, a thermal spring is a *new* or *nascent water*, formed by the combination of hydrogen and oxygen at a great depth in the earth's crust and at high temperatures. This may account for the fact that it differs from other waters in its solvent power and in its chemical and physical properties. The hot spring is described as an attenuated volcanic eruption. It often gathers salts in the more superficial strata through which it passes, but it brings to the surface from a great depth metals and metalloids and gases which are not met with in other springs; and its physical qualities include not only natural heat but electrical properties and radio-activity.

We have at Bath and Buxton valuable waters of this kind. Recent investigations into the properties of thermal waters should therefore be of much interest to us. Just as the old question used to be discussed whether saline water could be artificially reproduced, whether in short there was any real value in the natural product, so the same question was asked about thermal waters. Are thermal baths in any way different from water artificially heated? Five and twenty years ago, in a valuable book on British spas and climates, prepared under the auspices of the Royal Medical and Chirurgical Society, this question was raised by the late Dr. Ord. Dr. Ord thus expounded the doctrine of that time: "We take it that the idea that telluric heat has in itself any peculiar therapeutic value, and that water rendered hot by nature is in any different physical state from the same water artificially heated, cannot now be entertained." But, later on, speaking of the gases contained in thermal waters, he asks: "Is it possible that nitrogen dissolved in water and free from the opposition of oxygen may exert a sedative action on the surface of the body? Or is there, after all, something in this alleged telluric heat, conferring on nitrogen issuing in the thermal waters some new qualities, dependent on some allotropic change, which gives a special virtue to the baths?"

Not long after Dr. Ord wrote these words argon and helium, elements allied to nitrogen, were found in the waters of Buxton, and in 1898 came the discovery of radium. In due course many medicinal waters, and in particular those thermal waters which from their very insignificant content of mineral matter had long been known as "indifferent thermals," were found to contain these new elements and to be radio-active, sometimes to a remarkable extent. Fresh from the source, they show not only the energy of heat at a precise point of temperature, but this other elusive form of energy. And both are soon lost. The late Sir William Ramsay has given us a full account from the physical side of radio-activity in the waters of Bath. The properties of radio-activity on the medical side have not been as yet worked out, but there is reason to think that it is a factor in the action of certain medicinal waters.

Fruitful investigations have been commenced in another direction. It has been found that metals and metalloids are present in many waters in what is known as the colloidal condition. We now know that many active elements like arsenic, iron, sulphur, barium, copper, silver, zinc—even when present in extremely minute quantities in a colloidal condition—exert a power altogether out of proportion to their bulk—for example, in destroying micro-organisms or arresting their activity. It is now possible to observe with the ultramicroscope active particles of arsenic, sulphur and other elements in natural waters, and to measure the size of the particles and the speed of their movement.

It is sufficient only to name these two investigations in order to show that a door has been opened for further research. If we desire to understand medicinal waters we must know, not only what are their physical properties, such as heat, electricity, and radio-activity, but also what is their chemical constitution and the association or dissociation of their elements, and what elements are present in a colloidal condition. It is not difficult to believe that this new knowledge will in time account for the estimation in which many thermal waters have been held for two thousand years.

The waters of Bath are the most remarkable of their kind in Northern Europe. Their high temperature and abundant flow admirably adapt them for *thermal treatment*. Thermal treatment, strictly speaking, means subjecting the body to the action of natural thermal waters, with their various chemical and physical properties to which I have referred. It will be readily understood that thermal treatment is a two-edged weapon, and that it may produce either good or ill effects according to the skill with which it is handled. Baths must be dosed as accurately as drugs, and their effects as closely watched. In my opinion natural hot baths are more valuable than any others in the treatment of chronic disease.

All good thermal spas like Bath are very ancient. Hot springs are not easily overlooked, and they were most of them discovered by the Romans. But with all its merits antiquity has its drawbacks. I have often thought that it is sometimes rather difficult to keep an ancient spa up to date. Science advances, and time and men's needs are changed so rapidly that the appliances of a first-rate spa must needs be renewed almost from generation to generation. How shall this be done when the ground is cumbered with the relics of many centuries? It is necessary to let the ruins, however stately, stand aside, and let the ever-new water find a new habitation. In my belief the waters of Bath are a unique possession in England and worthy of the best setting that it is possible to give them.

Much that I have already said upon thermal springs applies as much to Buxton as to Bath. The two spas are, however, sharply contrasted in their relation to the temperature of the human body. Buxton water is some 15° below blood heat; Bath as much, or more, above blood heat. The difference of climate intensifies this contrast. Bath has a sedative and valley climate. Buxton, at an elevation of 1,000 ft., is the most tonic spa in the British Islands. It follows that for most people Bath is preferable in the colder months of the year, and Buxton in the summer; and it also follows that Bath is in our country the spa *par excellence* for thermal and hyperthermal actions, and that Buxton is equally well adapted by nature for what have been described as *subthermal* and tonic actions, which form so important a part in the treatment of invalids. I have already referred to the richness of the sky-blue water of Buxton in nitrogen gas and its congeners and in radio-activity. It also contains a number of metals, and would be an inviting field for the ultramicroscope. The waters of Matlock Bath are of the same class, but considerab.y cooler.

Another class of natural waters is composed of those that depend for their medicinal value chiefly upon the element sulphur. We have no hot or thermal sulphur springs like the famous New Zealand waters and those of the French Pyrenees, but the British Islands are rich in cold sulphur springs. Of these there are two kinds, which are called respectively the *pure* sulphur waters, such as those at Strathpeffer in Scotland, Llanwrtyd in Wales, and Lisdoonvarna in Ireland, and the *salt* sulphur waters, represented by Harrogate and Llandrindod Wells.

Harrogate is a spa of the first magnitude, both as regards the quality and number of its springs (about eighty in all) and the excellence of its equipment. I know no group of similar waters in any country more remarkable in number and variety than those which rise within the space of a few yards in the "Bog-field" at Harrogate. In these springs both sulphur and salines are present in varying proportions, so as to afford a variety of combinations, suitable for different forms, more particularly of gouty and rheumatic and digestive disorders. The climate of Harrogate is tonic and well suited in summer for delicate persons.

The waters of Strathpeffer contain but little saline matter, but are very strong in sulphur. They are therefore appropriate, where it is desired to obtain the uncomplicated effects of sulphur water, in internal or external application. The cool summer season in the northern latitude and the fine air of the North of Scotland no doubt contribute to their effect.

In addition to the spas that I have noticed, there are many less known sulphur waters in Britain. They abound in most counties. I wish to emphasise the importance of this particular class of spas. It would, I think, be hard to find in the whole range of medicinal waters an ingredient of so much remedial value as sulphur. This may seem a confident assertion. But it rests upon a large number of observations which I had an opportunity of making during many years at one of the smaller British sulphur spas. Many of the poor people and the farmer folk in the neighbouring counties suffered with rheumatism, and I was able to confirm beyond question their own statements as to the relief they obtained both from sulphur waters and baths. I also remarked that a large number of patients of a different class resorted to the same waters for gout and gouty ailments. Year by year experience showed that gouty as well as rheumatic disorders were definitely amenable to treatment by sulphur waters.

It is, therefore, a happy circumstance that in a country like ours, where rheumatic and gouty affections are especially prevalent, the provision of sulphur waters is so varied and extensive.

We now come to the British waters which are chiefly salt or saline. I have already mentioned that some of the sulphur waters contain a proportion of salt, which modifies their action. But quite apart from these wells of mixed constitution, the great class of salt waters in which table salt is the chief ingredient is well represented in Great Britain. There are, it is true, no hot or effervescing salt springs in our country, like those that have been so much used abroad in the form of baths, for disorders of the heart and circulation. I can only say here that the medical value of such baths, whether natural or artificially prepared, is in my opinion proven. A large number of persons affected with maladies of this kind can be treated with great advantage by hydrological remedies. The familiar "disordered action of the heart" of soldiers is a case in point. During the last six months this troublesome condition has been treated with good results by the sedative pool bath. Certain Continental spas with salt waters, like Nauheim, have in recent years become famous for the treatment of such disorders. It will be readily understood that in cases of this kind baths must be given with care and precision. No routine

treatment is admissible, and every case requires careful medical supervision at all stages. Such conditions cannot be guaranteed at every health resort. But I am confident that, given these necessary conditions, cases of disordered heart and circulation can be as well treated within the British Islands as at any Continental spa.

The British salt waters are cold, like those of Bex in Switzerland and Salsomaggiore and Kreuznach. They show a variety of composition, and are to be found in all grades of strength. The water, or rather the nearly concentrated brine, of Droitwich is drawn up from the deposits of what was probably once an inland sea or lagoon. Such brines are too strong for internal use, but furnish a powerful means of what is known as *surface treatment*. From their action upon the surface of the body they indirectly stimulate the deeper tissues, and produce a favourable reaction in certain chronic diseases. This principle and the practice founded upon it have been carried much further at foreign salt spas than with us. I will only refer to the Limans on the Crimean coast and to the Scandinavian spas. Weaker but valuable brines are available at Nantwich and Stafford. Salt waters of a potable strength are found at Woodhall Spa, containing other important ingredients, such as the chlorides of magnesium and calcium and also iodine. Llandrindod Wells and Leamington may be here mentioned, for although very different in other respects they are alike in one important matter. The saline strength or grade of both these spas, which are too little appreciated, happens to approximate very nearly to one per cent. This is the strength or *tonicity* of salt in the fluids of the living body. Therefore waters having a similar tonicity offer what has been called a "natural serum," and should be helpful in irritable conditions of catarrh of the mucous membranes.

Every spa physician has remarked the powerful influence of climate upon hydrological treatment, and especially upon the effects of baths. The same bath has very different effects, according as it is given in the summer time, let us say, in the Rhine Valley at Nauheim, beyond the Grampians at Strathpeffer, or at 5,000 ft. above the sea at Bormio. Spa treatment is everywhere modified by the local climatic conditions. It is, therefore, important to remember that the British spas are located in a tonic and invigorating island climate. All British health resorts are tonic, relatively to those of the Continent, and therefore as a rule the treatment is more invigorating than similar treatment taken abroad, and the need for an "after-cure," so often emphasised at the French and German resorts, is not so much felt. Within the shores of the British Islands there is, however, quite enough variety of climate to give some of the spas a more tonic and others a more sedative action, which is a matter of considerable practical importance. It is because, as a whole, the British spas are comparatively cool and bracing that they offer to our friends across the Channel, as was suggested some years ago by Dr. Neville Wood, not only an invigorating treatment but a pleasant and healthful change from the heat of the Continental summer. I have a vivid recollection of the interest manifested by parties of French physicians, who were conducted to some of the Scottish and English health resorts after the International Medical Congress in the year before the war. I know of no reason why the British spas should not become places of European resort. May I add here that experience both of British and Continental spas more and more shows the value, not only of large and highly-equipped establishments, but also of simpler and smaller spas? There is room for all. No health resort, however well provided, can meet the indications of all cases. On the other hand, there are some unpretentious places which offer few means of treatment, but they suffice for those that need them. Moreover, especially in the present days, rest is sometimes a necessary ingredient of the cure, and a restful spa is wanted. There are in Britain many small and restful spas, having active waters and good provision for baths. It would be a mistake to regard these places as in their own way less valuable than the larger health resorts.

Dr. S. Sunderland, in his book on the "Spas, Baths and Wells of Old London," has shown how common it has been for spas famous in their day to undergo a temporary or permanent eclipse. Many and various factors contribute to the reputation of a health resort. When from any cause this reputation has declined, it sometimes happens after many years that the waters are investigated and their merits brought to light. The spa is rediscovered, and established on a basis of more exact knowledge. No other foundation can of course be possible for an acceptable method of medical treatment, and, as we shall see immediately, there is nothing more desirable in regard to the British spas than a systematic determination of the scientific basis of the actions of waters and baths. Some spas have already undergone this process of redis-

covery with the advance of knowledge, and others will probably undergo it. It is not unlikely that some British waters of which little has been heard for many years will be again brought into use. Cheltenham has abundant springs of a mild saline water, which are well adapted to digestive and gouty disorders. One of these springs contains bicarbonate of soda, and is the only alkaline water in the British Islands with which I am acquainted. Bridge of Allan, again, possesses an unusual type of salt water, of which the density or tonicity closely corresponds to the fluids of the body. I should also anticipate a revival of the use of chalybeate waters, of which there are many in our country, not forgetting the once famous water of Tunbridge Wells.

Lastly, there is a British water different in kind from any of those already mentioned. It resembles certain much-frequented waters in the Vosges Mountains, and is very similar to that of Evian-les-Bains, on the Lake of Geneva. All these waters contain only very minute quantities of mineral constituents. Their whole action is not to bring matter into the body, but to dissolve and eliminate matter from the body. They are powerful solvents, and in these days, when toxic disease is so prevalent, natural solvent waters must have a place in the field of hydrological medicine. The increasing use and reputation of solvent waters on the Continent of Europe may well lead us to anticipate a similar development in the British Islands. The water which I have in mind does not stand alone in this country, but it is the chief of its kind. It is the St. Anne's Well at Malvern. In my opinion it is quite as efficacious as that of Evian-les-Bains. As we now know, all waters are most active fresh from the source. Bottled waters are second-rate at the best. I am disposed to think that there exist at Malvern all the necessary elements for a first-rank spa having these desirable properties. It is a water well adapted for all cases requiring eliminative treatment. I need not specify the various forms of illness in middle and later life for which solvent waters of this kind are prescribed. The Malvern Hills offer, in addition to the water, an air of bracing quality, which has been recently shown to be almost unrivalled for purity in England. The fine quality of the air has long been recognised, and the climate and beauty of the locality have long ago placed Malvern high in the rank of British health resorts. What I think remains to be recognised is the fact that the water is of such a kind as to give it a useful place among the British spas.

Soon after the war broke out a committee of the Royal Society of Medicine, in its Section of Balneology and Climatology, was appointed to inquire into the existing facilities for the treatment of soldiers at the British health resorts, and by physical methods in general, and to advise the War Office in the use of these facilities. Authoritative advices of a complete and deliberate nature were issued both to spa practitioners and to the staffs of military hospitals, which should serve as a guide to them in the employment of British waters and baths for soldiers, whether wounded in various ways or invalided from the Front. Local committees were formed in the health resorts, and case record cards were prepared and freely supplied for reporting the treatment of such cases upon a simple and uniform system.

At all the localities, from the beginning, every facility was freely placed at the disposal of the wounded. Local authorities and private owners vied with one another in this effort. The work of the committee has been rather confined to assisting in making better known the benefits that accrue from adequate treatment of this kind, to the selection and distribution of cases appropriate to different places, to recommending the provision of new and better methods of treatment, and to setting up for the first time in connection with the health resorts a proper system of case records. In some of these matters difficulties have naturally been encountered, and the work is still unfinished. At a recent meeting of the Royal Society of Medicine reports have been presented, and others have reached me direct from the spas, which give some idea of the magnitude of the work that is already being accomplished for the wounded. At Bath 2.220 soldiers have been treated by waters up to the middle of November. Even larger numbers (3,500 soldiers) have been received into the hospitals at Harrogate, but only a certain proportion of these have used the waters and baths, as some of the hospitals at Harrogate are devoted to acute cases. I may here say that it has seemed to the London committee that, considering the number of soldiers who really require spa treatment, it would be better, as a general rule, that the various hospitals at the spas, which are not too numerous, should be reserved for spa invalids, otherwise it may well be that men who urgently need treatment for stiff limbs, shell-shock, rapid heart, or rheumatism are kept out by surgical cases that might

as well be treated elsewhere. A recommendation to that effect was made to the Army medical authorities. At Buxton, in the first two years of the war, 1,926 men were treated in the Devonshire Hospital. At Buxton also a very interesting new departure has taken place in the erection by the Canadian Government of a special hospital for Canadians suffering from wounds and ailments requiring hydrological treatment—that is to say, the expert use of waters and baths and other physical remedies. I am informed that up to date 67 per cent. of the men treated in this manner have been returned fit for duty. At the salt baths of Droitwich, 17,102 free treatments have been given. Woodhall Spa, with limited accommodation, has treated 267 cases, and the Highland Moor Red Cross Spa Hospital at Llandrindod Wells 307 cases in fifteen months. Many other soldiers have been treated at Leamington and Cheltenham; and at Strathpeffer 150 cases of rheumatism and other ailments for which treatment by sulphur waters and baths is appropriate have been treated.

I may here mention that, altogether apart from the work at the mineral spas, there has been during the past two years a great increase of hydrological treatment in Great Britain and Ireland to meet the needs of wounded soldiers. A new form of local treatment by means of moving water at varying temperatures has been introduced into this country and greatly developed. "Whirlpool Baths," as they are now called, have been widely used for stiff and disabled limbs. Also a large "sedative pool bath" of flowing water has been devised for the treatment of disordered action of the heart and for shell-shock and nervous affections. And under the auspices of the same committee these local baths and sedative baths, and others of a more stimulating nature, have within the past year been installed in many places where wounded men are under treatment, including the Command Depots at Tipperary and at Heaton Park, near Manchester; at the Canadian Hospital at Ramsgate; and at the great Red Cross Hospital at Netley; and at Red Cross clinics in Brighton and London.

The use of these hydrological methods has already proved of much value, and under expert medical direction is likely to take an important place in the treatment of disabled soldiers.

Those who are acquainted with the British spas will acknowledge that some are already admirably utilised; whilst others, perhaps of equal merit, are capable of further development. Some, like Bristol Hot Springs and Scarborough Spa, belong to the past; some, I think, belong to the future. It is a matter of much satisfaction that good and solid war service has been accomplished during the last two years by means of remedial baths, combined as they should always be combined with other forms of physical treatment, not only at the spas but throughout the country. In these matters it is evident that a new development is taking place. In what direction, then, are we moving? Let me remind you of the natural evolution of the modern health resort. It began in the nineteenth century. Where in previous centuries only dignitaries and wealthy persons used to resort year by year with their great equipages, railways began to bring the people. The nineteenth century also witnessed everywhere a reaction from heroic methods of treatment, and all classes began to turn more and more, with instinctive confidence, to natural and physical remedies. At the spas, where there had been only tens and hundreds, scores of thousands of health seekers presented themselves; and not only at the spas, but wherever the use of water in any shape or form was set up. Many systems of treatment were bravely built upon the sands of ignorance, and unfortunately the lack of knowledge was badly compensated by excess of zeal.

Then, in the middle of the nineteenth century, two new sciences arose—it was high time—to join the large circle of sciences that are handmaids of medicine. These are to-day the two sciences of the health resort—climatology, which deals with the air, and hydrology, which deals with the water. I do not mean that those who had handled this form of practice in previous years were not endowed with much wisdom and long experience, but unfortunately for the most part their knowledge was an individual possession, and died with them. In the nineteenth century the facts began to crystallise out in a permanent form.

I have already incidentally mentioned some of the investigations that have been made into the properties of waters. Of even more fundamental importance are the researches of Winternitz and his pupils into the action of heat and cold upon the human body. If we are to use, as we are using, external surface treatments, we ought to know the effect, not only of temperature upon the body, but of salts and gases, and the effects of mechanical stimulation and movement. All these things are capable of exact determination. Hydrology deals with the

action and uses of waters of every kind, both within the body and external to the body, and since physical actions are exerted chiefly in the medium of water, these forms of treatment also come within its scope.

In Italy and France, Austria and Germany, during the last fifty years, this science has had many disciples, and has received the welcome to which all sciences are entitled. It is now taught in the universities of all these countries, in one form or another. In France there is one eminent Professor of Hydrology at the University of Toulouse, annual courses of lectures at other universities, and an Institute of Hydrology has now been attached to the Collége de France. In Germany facilities for this teaching are provided at ten or twelve of the universities. In Austria-Hungary there are professors of "Hydrotherapy," or "Balneology," at Vienna and Prague, besides lecturers in other universities. Italy has systematic teaching in at least five universities, and a professor at Rome.

On July 21st, 1914, a few days before the outbreak of war, a memorial was laid before the University of London, recommending the establishment of a University Chair in Medical Hydrology and Medical Climatology. That proposal is still before the Senate. Those who were responsible for it believed that London, as the capital of an Empire rich in climatic resorts and in medicinal waters, was the natural centre for the proposed teaching. They knew that one of the aims of the University of London was to supply means for instruction and research in subjects that are not dealt with in the individual schools. They held that, taken together, these subjects form a branch of medicine of such importance that it ought to be systematically taught; that the absence of proper teaching in medical subjects was the source of many evils, and opened a wide door for empirical and irregular practice. They therefore proposed that a Chair should be established in London, and that authoritative teaching should be thereby provided for senior students and practitioners who were likely to specialise in this branch of practice, as well as for medical men who came from the country or from distant parts of the Empire; and also that laboratory facilities be provided for research work upon British soil. The memorialists pointed out that in this country alone the student and practitioner are without any means of special instruction and research, and called attention to the fact that in India, South Africa, Australia, Canada and New Zealand there are large numbers of waters and climates of the first importance awaiting scientific study and recognition.

These considerations appear to have gained weight and force from the experience of the war. I have alluded to the use of physical remedies for soldiers. They will probably be much more extensively employed. These are highly-specialised forms of treatment. Where are the specialists? The need is not met by setting up a "whirlpool bath," valuable though that may be for a disabled limb. It is the worst error in physical treatment to think that one method is applicable to all conditions. We want trained men who have studied the principles and practice of hydrological medicine.

Again, what will be the effects of the war upon British spas? Quite apart from wounded soldiers, a new and great demand will be made upon them. The tide of British invalids and health seekers that has set for so many years to the Continent has been turned back. To what extent can the spas of the British Islands meet this new demand? As a physician I am only interested in the scientific side of these problems, but it is difficult to resist the conclusion that the case for teaching put forward two and a half years ago has become, if anything, more urgent. It must be confessed that physical remedies are too little understood and therefore too often misapplied. Is it not obvious that no branch of medical science, or the art that is dependent upon it, can be in a healthy condition if it is not taught? I venture to go further, and say that it cannot be in the public interest that any form of medical treatment should be practised unless its elements are taught. I would submit that in this field science and practice have been far too much divorced. They should go hand in hand. May we not hope that the time has now come to lay the foundations of a British School of Hydrology, which shall embrace in its scope not only the British Islands but the Empire at large?

DISCUSSION.

THE CHAIRMAN (Sir Thomas Barlow, Bt., K.C.V.O., M.D., F.R.C.P., LL.D., F.R.S.), in opening the discussion, thought everyone would agree that the Society had done well in taking up the subject of British mineral waters as a definite asset of the Empire. Anyone who took the trouble to glance over a geological map of these islands would be struck with the fact that, in coming down from the north-west of Scotland to the south-eastern part of England the outcrop of almost every geological formation was present, and that in itself was an index of the enormous wealth of mineral constituents that lay at our doors, especially in

the form of mineral springs. The war, and what would follow the war, helped to accentuate the need of our becoming acquainted with this great inheritance. Not only in that but in many other ways the people of this country had been far too idle in realising for themselves what an extraordinarily rich country they lived in, which would respond to knowledge, to investigation, and to courage in a way that was quite remarkable. The author had envisaged the subject in a fundamental manner; he had drawn attention to the variety and richness of the mineral waters, and also to the remarkable variety of climate that the British Isles possessed. So far as the practical use of mineral waters was concerned, he desired to call attention to the wonderful coast-line that the British Islands possessed, which afforded such splendid opportunities for subsequent recuperative methods after the use of saline waters.

Mr. H. H. Spiller (Messrs. Thos. Cook & Son) thought the information contained in the paper would be a guide to the medical profession generally in connection with the different spas which were suitable for various complaints, and might lead to specialists living at the spas who were specially trained for the treatment of the diseases dealt with. One weak point connected with the spas of this country was that they were not carried on seriously apart from the professional branch. There ought to be more co-operation between the municipalities, the hotel-keepers and the professional men who were doing their best to establish the reputation of any particular spa. At the most renowned Continental spas the patient at once went to the doctor, who drew up a paper giving particulars of the treatment and *régime*, and those particulars were communicated to the authorities who ran the baths and to the hotel proprietors. Instead of having one *table d'hôte* in the hotel for everybody. there was a general *table d'hôte* for the people who were not invalids, and a special table for each of two, three or four particular treatments that were being undergone by different patients. In this country, on the other hand, we seemed to cater only for the general traveller, the tourist and the tripper. When an invalid went to a hotel he was looked upon as an individual who required more attention than other people, and was consequently charged more. That did not encourage patients to go to those places. If the medical profession took the trouble to recommend particular spas to their patients, and specialists were there for the treatment of the different complaints, he thought they ought to be more supported by the hotel people in the town, with the endeavour to attain their object—namely, the cure of different diseases and an increase in the number of visitors.

Mr. John Hatton (Director of the Baths, Bath) thought that in the future spa treatment would become more and more scientific. Research work would be carried out, like Sir William Ramsay's investigations into the radio-activity of the Bath waters, and like the work which he believed was being carried out in connection with the Harrogate springs, so that more would be discovered about mineral waters. Side by side with that, pathological research would be carried on; the range of diseases successfully treated by mineral waters would be widened, and the technique of administering the treatments would be still further improved. Much had been done on those lines already, and the leading spas now possessed highly trained and thoroughly efficient staffs of attendants and masseurs. By those means the percentage of successful cases and cures would be increased, confidence in spa treatment would be strengthened, and British doctors would realise that their patients could get quite as effective treatment at British spas as at the once fashionable German resorts. People had been driven to realise during the past two years that the springs of this country could cure them as effectively as—in many cases more effectively than—the foreign waters, and thousands of men had come to appreciate the value of spa treatment who had hardly heard of it before. In the second place the British spas would widen the field from which they drew their visitors. They would cater for French and Russian visitors to a greater extent than before; it looked as if American visitors would prefer British to German waters, and a growing number of guests would be welcomed from the Overseas Dominions. He hoped the combination of British spas which had recently been started would continue, and by combined advertising make a strong concerted effort after the war to attract foreign visitors. If that were done thousands of pounds would be brought into this country, as some of the German spas had in the past almost entirely been supported by British and Russian visitors. In each place the municipality, the hotels, the apartment houses, the amusement caterers, the shopkeepers and other business people, and certainly the medical profession, must realise that they were all in it for the general good of the place, that their success depended upon the success of the spa, and the success of the spa depended upon them. From the national point of view he thought British spas generally would realise that by combined effort in many directions they could accomplish work of real value not only to themselves but to the whole country.

Dr. W. Bezly Thorne said he could look back on the time when, with the exception of a perfunctory attempt to give some instruction in gynæcology, there were no special departments in the general hospitals of England. Little by little the hospitals had added departments for the eye, the throat, the ear, for dentistry, for the application of electricity, for pharmacology, and the study of bacteriology; but there was no single systematised instruction in hydrotherapy, or any installation in the hospitals upon which the first elements of that

science could be taught. There was no body of men in the world more highly cultured, better educated, and more devoted to the execution of their responsibilities than the medical profession in England; but to a very large proportion of them hydrotherapy was a closed book. That was an immense misfortune at any time, especially at present, when thousands of gallant men were returning home from the war broken in health, worn out in mind and with shattered nervous systems. Hydrotherapy covered a range of diseases and of affections such as none other of the specialisations could attempt to touch in number and application. Hydrotherapy would influence the course of all the specific fevers, especially those to which childhood was prone; it had a paramount influence over all those chronic affections which were classed as gout and rheumatism; it was the pre-eminent remedy for affections of the heart and the blood vessels, and for that hydra-headed and distressing class of affections classified under the name of "neurasthenia," which apparently some people in the present day wished to attribute entirely to psychic causes, although they were due to physical and toxic causes. It was difficult to realise the extent to which that state of ignorance on the subject of hydrotherapy operated at the present time. In his opinion there should be no general hospital or institution for the education of medical men without systematised instruction in hydrotherapy, and an installation by means of which the principles of hydrotherapy could be put into practice and administered for successive generations of rising medical men. Those institutions and installations should not in any way compete with the excellent spa establishments, but they should educate medical men in the range of application of hydrotherapy and how to select the cases. By such means hydrotherapy would be raised to the level of a science, and British spas would come into their own and enjoy that appreciation and patronage which they so well deserved. After twenty or twenty-five years' experience of hydrotherapy, and knowing something of both foreign and British spas, he could not think of a single affection which yielded to hydrotherapy which could not be as well treated in the British Isles as it could be abroad.

Dr. J. Campbell McClure said that his recent experience in connection with hydrotherapeutic work in the Army had proved that those who dealt with the subject had to fight against the ignorance of the average practitioner of medicine, whether civil or military, and the ignorance of those in authority on anything connected with hydrotherapy. That was not the fault of each particular individual authority or practitioner of medicine, but of the system, and it seemed to him it must speedily be corrected if the country was properly to develop along scientific lines. Systematic teaching of hydrotherapy must be established, because hydrotherapeutic methods were not mere playthings. Properly applied, they did an infinite amount of good; improperly applied, they did an infinite amount of harm. He had come across cases recently which had been handled badly in institutions which professed to supply therapeutic treatment, with the result that the country had probably lost good officers for a long time, and perhaps permanently. Hydropathic installations were being placed in the care of excellent men, but men who, until the time of their appointment, did not know one end of a bath from the other from a medical point of view. A very close co-operation between the municipality and the medical profession was absolutely necessary for the proper development of the spas. Just as education was necessary for the medical profession, in a far greater degree was it necessary for the municipalities. They were ignorant of the fundamental principles of medical practice, with the result that a great many health resorts in this country, spa or climatic, were rendered ridiculous by the amusements provided by the municipality for the entertainment of their visitors. There was no attempt—as in German, Austrian, French or Italian spas—to make the place attractive and yet at the same time keep it definitely therapeutic. It was possible to learn in that respect, as in many others, from Germany. German municipalities had the sense to be advised by scientific men, and just in so far as the municipalities of this country carried on their present independent Gadarene course, so the British health resorts would utterly fail.

Mr. J. H. Hollyer (Droitwich) said that, as the lay director of one of the baths at Droitwich, he much appreciated the opportunity of hearing what their medical friends, to whom they always looked for a lead, had to say on the subject of hydrology and the general treatment at spas. Much would be gained by still greater co-operation between the medical men and those responsible for the direction of the spas. He was glad to hear that the medical profession was about to give more attention to advisory matters in connection with spa treatment than had been given in the past. There were many medical men who knew that spa treatment effected certain results in particular cases, but they did not know the action or the nature of the particular baths, and cases were sometimes sent to spas where it was impossible to carry out the prescription of the doctor that had sent the patient. Those responsible for the lay direction would therefore much appreciate the effort which medical men intended to make to educate themselves in spa treatment. It was also urgently necessary that there should be closer co-operation than there had been in the past between the hotel proprietors and those responsible for the management of the spas, so that the treatment could be properly carried out. By that co-operation not only would the medical men gain by the better results which would be obtained, but the owners of the spas would also profit.

DR. M. O. ATKINSON (Leamington) said that he represented both the medical profession and the municipality, as he happened to be the Mayor of Leamington. Mr. Spiller's remarks were absolutely true, that as a rule the municipality knew nothing whatever about the baths. They ran them as a sort of mercantile enterprise. He was sorry to say, however, that the doctors were nearly as ignorant. If a doctor tried to run a spa properly he was immediately sat upon by his brother practitioners because they thought he was trying to benefit himself. It was high time that some sort of system should be adopted, but it was difficult to know what to do. One doctor recommended one particular system and another doctor the exact opposite. He hoped the balneological section of the Royal Society of Medicine would endeavour to arrange for the proper *régime* that should be adopted at each class of bath.

MR. CARMICHAEL THOMAS thought the reason British spas were not places of European resort was that they did not advertise as the Continental spas did. All over the Continent and England most charming advertisements were to be seen of Evian-les-Bains, with the result that people flocked there. If English spas desired to make themselves popular, the best way of doing so was continuously to advertise.

CAPTAIN M. DALE though it was necessary for the doctors at British spas to obtain more power than they at present possessed. At Carlsbad, for instance, the doctor did not hesitate to go into the hotel and investigate the patient's food if he had not been making satisfactory progress. That was not sufficiently done in the hotels at the spas in England. The hotel proprietors in this country wanted the patients to take the ordinary *table d'hôte* meals, and do the thing properly for the benefit of the hotel, to the detriment of the patients. The reason so many people went abroad was because they wanted to get the benefit of the treatment, and because they got better treatment abroad than in England. A German doctor told him that English people made the best patients in the world, because they did what the doctor told them, but they could not do so in England because of the hotel proprietor.

MR. HENRY D. ROBERTS (Brighton) said he desired to say a word in defence of the municipalities. It must not be forgotten that at most Continental spas there was a tax, which yielded a considerable revenue to the town. If Brighton taxed every visitor 1*s*. a large sum of money would be obtained to advertise the town. It was no use, however, advertising a town unless the visitors had something to interest them when they got there, and one of the reasons that German spas had been so popular in the past was that, in addition to the spa itself, there were other attractions, such, for instance, as the wonderful opera house at Wiesbaden. It must also be remembered that spas were an accessory to the town, and that the town was not an accessory to the spa. Although Droitwich possessed baths by means of which people were cured of diseases, it was also the centre of the salt industry, and made its living out of that. The fact that there were spas in a town sometimes made people lose a sense of their due proportion; they thought that, because the springs existed, all other interests must be put aside. The healing side in those cases was more or less of a side line in the actual business of the town, and people had to make their living in other directions. He was sure that the municipalities would, if they were approached, be only too pleased to co-operate with the doctors. If, as a result of the meeting, the doctors could get in touch with the recently formed British Association of Health Resorts, some good would, he thought, result. It was necessary that action should immediately be taken, because the spas on the Continent were at the present time issuing millions of pamphlets with the object of drawing people from this country to their spas after the war.

MR. E. J. BURROW (Cheltenham) said that Cheltenham was a most extraordinary example of a spa not being taken seriously. When war broke out the Corporation did not take the matter up properly, and a body of tradesmen thereupon subscribed about £2,000, so that the spa could be run. They actually went so far as to furnish the spa and to supply a band. Some of the doctors in Cheltenham did not believe in the waters. For a long time he suffered from colitis, and on asking the doctor if he should try the Cheltenham water he said, "You can if you like." As a matter of fact, it cured him. He told the doctor, who was quite pleased, but he knew nothing of its action. He thought the author had taken a right step in trying to get the medical profession to take the matter up seriously.

DR. G. V. WORTHINGTON (Llandrindod Wells) said he felt that some doctors had been accused a little unjustly of ignorance. There were many medical men at spas who had made a special study of the subject, but a large number of patients were sent to the spas each year by medical men who had sometimes never been near the spa. Those patients went on for some time with the treatment that had been prescribed, and, finding it unsatisfactory, they blamed the medical man. The ignorance existed in the medical men who sent the patients to the spa, and not so much among the medical men who actually practised at the spa. Municipalities were also to a certain extent ignorant, but at Harrogate and Bath the municipalities were doing all they could to co-operate with the medical men to make the spas successful. Attention had been called to the fact that in nearly all Continental spas a tax was imposed, and in some cases in Germany the Government directly subsidised or supported the spas. In England there was no such encouragement

at all; the spas got on as best they could. Big places like Bath and Harrogate had more or less ample funds, but the smaller places were greatly handicapped, and it was difficult for them to spend much in advertising. If some special facilities were granted by the Government, he thought British spas would be able to do quite as well as Continental spas. He welcomed the prospect of the establishment of a Chair of Hydrology at London University, so that men who practised at the spas would be able to learn their work well. At all spas there were a certain number of medical men who came to the place without any previous knowledge; they did not take the trouble to go abroad and make a special study of the work before they began practice, and many patients no doubt suffered at their hands. On the other hand, there were at all spas a number of men who had taken the trouble to learn; they paid periodical visits to the spas abroad for the purpose of learning anything new and taking the utmost advantage of it, so that it ought not to go out from the meeting that people going to British spas could not be properly treated. At some of the bigger spas where the hotels had large numbers of visitors, the hotels did not pay much attention to the diet that was ordered for particular patients, but all the hotels at Llandrindod Wells undertook to carry out any diet that the medical men prescribed. In a great many cases, if the patients looked into their own consciences, it was more their own fault than the fault of the spa they went to if they did not benefit, because they disregarded the doctor's instructions in regard to the diet that should be taken. If the German and Austrian Continental spa business was to be captured, now was the time to do it; but unfortunately at the present moment the railway facilities had been greatly reduced. Previous to the recent alterations, a through carriage ran from Euston to Llandrindod Wells in five hours, but at the present time there was only one train a day from Euston, which took ten hours and involved three changes. At a conference recently held of the six chief spas the Board of Trade was urged to give reasonable railway facilities to them with a view to capturing enemy trade, and unless that was done not much progress would be made.

Mr. J. H. Hollyer endorsed Dr. Worthington's remark that the members of the medical profession at the spas themselves most conscientiously devoted themselves to the treatment of their patients. When he previously referred to the ignorance of medical men, he referred to those practitioners at a distance who did not know anything of the nature of the spas to which they sent patients, and thereby created the difficulties to which he referred.

Dr. W. Bezly Thorne said he also desired to add to his previous remarks that all honour was due to those medical men attached to the spas for the knowledge that they had acquired through their own personal study and observation.

On the motion of the Chairman, a hearty vote of thanks was accorded to Dr. Fox for his interesting and instructive paper.

Dr. Fox, in reply, after thanking the Society for giving him the opportunity of reading the paper, which had led to such a frank and useful discussion, and the Chairman for presiding over the meeting, said he had been greatly interested in Dr. Bezly Thorne's remarks with regard to the growth of special departments. He looked upon the branch of study with which he had dealt in his paper as a special department. Medical men at large could not be intimately and closely acquainted with the action of waters of baths, and the subject must be administered by specialists. It could be said with pride that British medical men held a distinguished place so far as their knowledge of the science of medicine and surgery was concerned amongst their colleagues in all countries, but it could not be gainsaid that the special branch with which he had dealt still awaited adequate cultivation. The war had brought into startling relief the necessity for the administration of hydrological treatment, and, unfortunately, knowledge of that subject was not widely possessed by the profession at large.

The meeting then terminated.

OBITUARY.

George James Drummond.—Mr. George James Drummond, who had been a member of the Society since 1868, died on January 31st, at his house at Penshurst, in his eighty-second year. His family has been connected with the Society since the year 1757, when Robert Drummond, a partner in the well-known banking house, was elected. The bank was founded in 1707 by Andrew Drummond, the father of Robert and John Drummond, the latter of whom joined the Society in 1762. The connection between the family and the Society has been continued from 1757—three years after its foundation—up to the present time. At the time of his death Mr. George Drummond was the senior partner in the firm.

In the year 1716 the Adelphi estate was sold by Sir Thomas Monpesson to the trustees of the will of Sir John Werden, who had two daughters—one of them, Lucy, married Charles, the second Duke of St. Albans, and the other, Charlotte, his brother Lord William Beauclerk. The third Duke's trustees granted a lease to the brothers Adam, who built the Adelphi and gave it its well-known name. John Drummond married a daughter of Lord William Beauclerk, and the Adelphi estate was devised to her by her nephew the fourth Duke (the son of Lord William Beauclerk). By this means the estate

came into the possession of the Drummond family. From John's son George, the estate passed to his son, his grandson, and his great-grandson George James Drummond. The original lease of the Society's premises terminated in 1867, and since that date Mr. George James Drummond has been the owner of the estate and the landlord of the Society.

COLONEL THOMAS HOLBEIN HENDLEY, C.I.E., L.R.C.P., M.R.C.S.—Colonel Thomas Holbein Hendley died at his residence in St. John's Wood on the 2nd inst., in his seventieth year.

He received his medical training at St. Bartholomew's Hospital, where he was Gold Medallist, and entered the Indian Medical Service in 1869. The greater part of his time was spent in the Rajputana State, and he was for twenty-four years Residency Surgeon at Jaipur. In 1897 he was Inspector-General of Civil Hospitals in the United Provinces, and from the following year until his retirement in 1903 he filled the Permanent Inspectorship in Bengal. He took a deep interest in the Ambulance Association of St. John of Jerusalem, of which Order he was a Knight of the Cross. He was also an ardent Volunteer officer. He was also widely known for his labours for Indian art. He organised the Jaipur Exhibition, and afterwards the excellent and well-planned Jaipur Museum. He wrote a number of works on Indian Art and History, including "Memorials of the Jaipur Exhibition" (four volumes), "Alwar and its Art Treasures," "Damascene Work in India," and "Rulers of India and Chiefs of Rajputana"; he was one of the originators of the *Quarterly Journal of Indian Art*.

Although Colonel Hendley only joined the Royal Society of Arts in 1916, he had for many years been interested in the work of the Indian Section. His first appearance here was in 1892, when he took part in the discussion on Sir William Moore's paper on Indian Sanitation, and from that time onwards he continued to speak at meetings or to contribute letters to the *Journal*. In 1914 he read before the Section a paper on "Indian Museums: A Centenary Retrospect," for which he received the Society's Silver Medal.

MEETINGS OF THE SOCIETY

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

FEBRUARY 14.—LAWRENCE CHUBB, Secretary to the Commons and Footpaths Preservation Society, "Highways and Byways." The RIGHT HON. LORD FARRER will preside.

FEBRUARY 21.—MRS. C. HOSTER, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment." LADY EMMOTT will preside.

FEBRUARY 28.—FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs." ROBERT HUTCHISON, M.D., F.R.C.P., will preside.

MARCH 7.—JAMES HARRIS VICKERY, LL.B., "German Business Methods."

MARCH 14.—DR. J. AUGUSTUS VOELCKER, "Fertilisers and their Supply in War Time."

MARCH 21.—G. W. JONES, "Colour Printing and some Recent Developments." CARMICHAEL THOMAS, Chairman of the *Graphic* and *Daily Graphic*, will preside.

APRIL 18. — HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

APRIL 25.—SIR FRANCIS FOX, M.Inst.C.E., "Flour and Bread." CAPTAIN CHARLES BATHURST, M.P., Parliamentary Secretary, Ministry of Food, will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

FEBRUARY 15. — PROFESSOR H. MAXWELL-LEFROY, M.A., F.E.S., F.Z.S., Imperial College of Science and Technology, "The Indian Silk Industry." The RIGHT HON. LORD ISLINGTON, P.C., G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

MARCH 15.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

APRIL 19.—D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

MAY 17.—SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

FEBRUARY 27. — ALFRED BIGLAND, M.P., "Imperial Assets and how to use them."

MARCH 27.—The HON. FREDERICK W. YOUNG, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee,

Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

GABRIEL GORDON CLEATHER, "The Drum."

DR. M. HORN, "The Belgian Colonies."

PROFESSOR WILLIAM RIPPER, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

Syllabus.

LECTURE III.—FEBRUARY 12.—*The Nineteenth Century.* Paris under the Empire. Vienna—Ringstrasse and buildings. Berlin—Centre and growth. Washington, New York, and Chicago. England—Late Georgian and Victorian progress.

LECTURE IV.—FEBRUARY 19.—*The Housing and Town Planning Act,* 1909. Problems for solution. Procedure. Advice to promoters. Preparation of schemes. Architectural considerations. Examples of Garden City movements—Letchworth, Hampstead, etc. The problem of London.

HOWARD LECTURES.

Monday afternoons, at 4 p.m.:—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies: (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market." Two Lectures.

April 30, May 7.

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m.:—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 5, 12, 19.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor A. Beresford Pite, "Town Planning and Civic Architecture." (Lecture III.)

Brewing, Institute of (London Section), at the Birkbeck Restaurant, High Holborn, W.C., 7.30 p.m. Discussion on "The Season's Barley and Malts."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Mr. E. Savill, "The Defence of the Realm (Acquisition of Land) Act."

Electrical Engineers, Institution of (Local Section), Mining Institution, Newcastle, 6.45 p.m. Discussion on "The Metric System."

TUESDAY, FEBRUARY 13... Cyclists' Touring Club (Metropolitan District Association), at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.15 p.m. Annual Meeting.
8.15 p.m. Illustrated Lecture.

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Miss M. A. Czaplicka, "On the Track of the Tungus."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Pain and its Nervous Basis." (Lecture V.)

Photographic Society, 35, Russell-square, W.C., 8 p.m. Annual General Meeting.

Colonial Institute, Hotel Cecil, Strand, W.C., 8.30 p.m. The Right Hon. Andrew Fisher, "Australia—a Commonwealth."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7 p.m. Mr. R. Townend, "Frequency Changers."

Heating and Ventilating Engineers, Holborn Restaurant, W.C., 5.30 p.m. Mr. A. H. Barker, "Standard Methods of Testing No. 1."

WEDNESDAY, FEBRUARY 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. Lawrence W. Chubb, "Highways and Byways."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. L. Martineau, "Hydraulic Transmission."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Colonel S. A. M. Copeman, M.D., "The Prevention and Arrest of Infectious Disease in War Time."

Oriental Studies, School of, London Institution, Finsbury-circus, E.C., 5 p.m. Mr. L. D. Barnett, "Ancient India."

THURSDAY, FEBRUARY 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Professor H. Maxwell-Lefroy, "The Indian Silk Industry."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Mr. J. H. Owen, "The Home Life of the Sparrow-Hawk."

Chemical Society, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. G. Donnan, "The Mechanism of Chemical Change." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. D. J. Cassavetti, "Greece and the European War."

Historical Society, 22, Russell-square, W.C., 5 p.m. Anniversary Meeting.

Numismatic Society, 22, Albemarle-street, W., 6 p.m.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. 1. Mr. H. W. Hutchin, "The Wet Assay of Tin Concentrate." 2. Mr. J. J. Garrard, "Hydraulic Tin Mining in Swaziland."

FRIDAY, FEBRUARY 16...Royal Institution, Albemarle-street, W., 5.30 p.m. Very Rev. H. H. Henson, "Author's Dedications in the XVIIth Century."

Electrical Engineers, Institution of (Scottish Section), 207, Bath-street, Glasgow, 7.30 p.m. Dr. A. Russell, "Some Aspects of Lord Kelvin's Life and Work."

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Dr. W. Mason, "Alternating Stress Experiments."

SATURDAY, FEBRUARY 17...Royal Institution, Albemarle-street, W., 3 p.m. Dr. H. W. Davies, "The Mystery of Counterpoint." (Lecture III.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—February 9, 1917.

Journal of the Royal Society of Arts.

No. 3,352. VOL. LXV.

FRIDAY, FEBRUARY 16, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 19th, at 4.30 p.m. (Cantor Lecture.) PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." (Lecture IV.)

WEDNESDAY, FEBRUARY 21st, at 4.30 p.m. (Ordinary Meeting.) MRS. C. HOSTER, Hon. Secretary, Society for Promoting the Employment of Women, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment." LADY EMMOTT will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, February 12th, PROFESSOR A. BERESFORD PITE, F.R.I.B.A., delivered the third lecture of his course on "Town Planning and Civic Architecture."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, February 15th; The RIGHT HON. LORD ISLINGTON, P.C., G.C.M.G., D.S.O., Under-Secretary of State for India, in the chair. A paper on "The Indian Silk Industry" was read by PROFESSOR H. MAXWELL-LEFROY, M.A., F.E.S., F.Z.S., Imperial College of Science and Technology.

The paper and discussion will be published in a subsequent number of the *Journal.*

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, January 30th, 1917; The RIGHT HON. SIR JOSEPH GEORGE WARD, Bt., K.C.M.G., in the chair.

THE SECRETARY of the Section stated that all present were doubtless aware of the sad cause which prevented the Secretary of State for the Colonies, Mr. Walter Long, from fulfilling his promise to preside at the meeting. Sir Joseph Ward, the distinguished ex-Prime Minister of New Zealand, had very kindly consented to take Mr. Long's place.

THE CHAIRMAN, in introducing the reader of the paper, said there was no one more qualified to speak on the subject of Imperial industries after the war than Mr. Beale. In Australia he was recognised as one of the most enterprising men in the Commonwealth, and anything Mr. Beale had to say on the question could be accepted by everyone. In amplification of what the Secretary had said concerning Mr. Long, he was sure everyone would sympathise with him and his family in the great loss they had sustained. His son went down leading his regiment, fighting in a noble cause. Nevertheless, those who fell by the way created a void in the life of their families that probably could never be filled, and it would be some satisfaction to Mr. Long and his family to know that the sad cause of his absence was deeply felt by all those present. He would personally take the opportunity of conveying to him what he felt to be the expression of the feelings of the meeting.

The paper read was—

IMPERIAL INDUSTRIES AFTER THE WAR.

By OCTAVIUS C. BEALE,
Representative and Past President of the Australian Associated Chambers of Manufacture.

A worthy padre tells the following anecdote: "Mortally wounded at the Somme, a British Tommy wrote to me this last message: 'With a good heart I die for England.' When I first

knew that boy he was shoeless and his clothing hung in rags." An everyday commonplace story, glorified by the admirable patriotism and adorable self-sacrifice of the young man. But the story illustrates also diabolised or apotheosised *laissez-faire*, just as our individual politics may cause us to regard it. Some of us declare, whilst others deny, that it is the duty of the State to make sure of provision for all honest citizens—to see that each shall have opportunity to earn an income. Was justice done to that boy and his like before the war? And when it is over are we to revert to like conditions as being everyday and commonplace?

Several years ago a prolonged discussion, occupying three days, upon the question of Imperial Preference took place at a Congress of Chambers of Commerce and of Manufactures of the Empire held in London. The manufacturers of Canada pronounced themselves in favour of Preference, which necessarily involves tariff differentiation. The venerable Lord Avebury—since departed—in speaking against it, said that a great advantage which the children of the poor enjoyed in England, as compared with those of Canada, was that under the English system of free imports the food and clothing of the children were obtainable at the lowest possible prices. It fell to my lot to follow him, in speaking for the other side. I was able to say that, having visited all the Provinces of the Great Dominion, I had not seen one shoeless, half-clothed or half-fed child, for the reason that the avowed policy and practice of the governing powers are to see that their citizens be adequately protected in every form through life. Further, if the kindly nobleman, whom we all held in honour, would accompany me I would find him a hundred thousand children within a three-mile radius from Cannon Street insufficiently clothed and fed. The statement of the best-informed man in the United Kingdom—Mr. Charles Booth—that four millions of the people were submerged into starvation had never been refuted.

Well, then, the war has come to end or to extend that state of things. With all our troubles, it looks as if the whole people in the interim are as well, and even better, fed and clothed than they were before. We find huge workhouses, so-called, transformed into military hospitals, whilst the former inmates, we are told, have returned for the most part to real work and with very satisfying remuneration. Once more at the parting of the ways, the Mother Country must make a decision to protect or to neglect. All that is worth having is worth protecting. Nothing that is worth having may be neglected.

The phrase "Political Economy," so prolific in mischief to mankind, was used for the first time by Mountchrestien de Watteville in 1615. François Quesnay and his friends long after adopted and spread its use. Quesnay, in overhaste for celebrity, announced his discovery of the quadrature of the circle. It was a trifling solecism compared with that involved in the jumbled concept "Political Economy" itself. As we can have "household laws" (*oikos* and *nomos* = economy), so logically we can have national economy without overstraining the simple idea. And much of the enormous mercantile, manufacturing and maritime success of the Germans is due to the clear-sighted men Friedrich List, Gustav Schmoller and their co-workers, who threw overboard the fetish so worshipped in England, to establish in its place the sound principle of *Volkswirthschaft*. The only equivalent is our word "protection" in its widest meaning. In periphrase it means conservation of national interests, than which there is nothing more loyal and laudable. But that is in deadly opposition to *laissez-faire*, which phrase M. Yves Guyot declares to be "the first formula of political economy," the other exponents being in full agreement.

The late lamented William McKinley, a true lover of his country, only a week before his cruel death, said that during his Presidentship no foreigner could claim he was better off because of McKinley's fiscal policy, and no American citizen could say that he was himself worse off. From the American standpoint of isolation, that was a just and loyal claim. It is their traditional policy to take all they can, as a Government, and give nothing—quite defensible and very much defended. Our case is altogether different, for we have been fighting rapacious enemies by co-operating with true and tried friends, who with us have risked all for the common life and hope.

All that we owe to neutrals must be paid for in cash, for beyond humanity and friendship there is no more obligation to any of them than that implied in the succinct speech of President McKinley. Nothing venture, nothing have: whilst inversely our duty is to those who have ventured their all with and for ourselves. That is justice itself, and justice exalteth a nation.

It remains, then, to indicate in what ways we can and must assist, by forming a column

of mutual strength and support, the British family of nations and our glorious Allies.

Not merely the inconceivable losses brought upon the Allies by the great war, but the incalculable cost of restoration and the burden of pensions, added to the vast indebtedness that will be incurred hereafter by indispensable imports from neutrals at exorbitant prices, impel us to associate for the common relief. No indemnities that may be inflicted upon our enemies will suffice to recoup us. The most that can be obtained will be interest at a low rate upon the principal sum. The bill will be passed on to their posterity and our own.

The Illustration of Sugar.

But immediate help and strength will be found in development by each member of the Alliance of its productive powers, especially in what are loosely called raw products. Most of these are in themselves manufactured goods, yet they become, for the use of others, manufacturers' materials. Of such, one of the most important and illustrative is sugar. We may best study it in relation to the United Kingdom itself. And here let me say that there will be no attempt to treat this or any other item exhaustively, but rather to seek, by displaying concrete examples, to set forth the principle and effect of preferential Allied interchange.

The United Kingdom requires at least 2,000,000 tons of sugar per annum, and much more if her sugar-using industries are to be developed as they ought. Of these 2,000,000 tons, 1,300,000 came from Germany and Austria. The whole was imported, and Germans sent twice as much to us as we received from the rest of the world. You know the familiar story of British sugar-refining under political economy as against what it might have been under national economy.

Less than a century ago Britain refined all that she used. Thirty years ago we still produced five-sixths from imported raw sugar with the added benefit of the by-products. Of late only one half was manufactured in Britain, the industry falling into few hands and the others being frozen out by the free blasts of competition through our open door. The foolish foreigners —according to the gospel taught in our schools of learning—made a present to this nation by placing bounties upon exports, though with the avowed object of displacing our industries so as to retain a huge balance of national profit to themselves. They secured the turnover, enlarging the fertility of their soil for other products, encouraging the manufacture of machinery, providing cheap food for animals from the offal, remunerating chemists and furthering chemical research—these and other gains all at the same time, and all for Germany.

Yet the British Empire is well able to produce the sugar it requires. Disaster fell upon sugar-growers in the Crown Colonies, and had not our Oversea Dominions adopted a policy absolutely antithetic to that of the Mother Country, extinction must have followed there also. Canada came to the rescue of the West Indies, whilst Australia fought out not only the question of local production, but also that of the employment of white labour.

Whilst coloured persons, whose manner of life and forms of expenditure under very low remuneration added nothing to national strength and progress, were only able to turn out 80,000 tons a year, our white British Australian citizens have approximated a yield of 250,000 tons. The industry maintains a school of chemists of pre-eminent ability, and, moreover, workers and farmers are all well paid. Say the duty is two-thirds of a penny per pound, there are against that the great advantages of subsidiary trades, of support to steamer services, of cheap molasses for stock, of spirits for industrial purposes, of support to technical education and to advanced agriculture. And the entire gross value is extracted from the soil. Is that not enough? Why, then, allude to military strength, to multiplication of the British race, to the triumph of the industrial example? To say nothing of the fact that when the supreme trial of war finally came—as we knew it must come—the Australian citizen gets for threepence what now costs the *laissez-faire* Englishman sixpence. And all along the retail price of sugar in Australia was moderate.

Need we enlarge? Is the lesson not obvious? I am assured by the highest authorities in Mincing Lane that—apart from very probable rise in labour cost everywhere—a price of about £12 per ton for raw sugar, f.o.b. in the country of production, can be reckoned upon in the British Empire. In the French and British Possessions there are sugar lands yet to be reclaimed, and sufficient labour available to supply all possible requirements of the Allies. As already alluded to, the offal from the industry, both from cane and beet, is highly valuable for meat production—that want, of all others, which is sure to be accentuated in the coming years.

True, the sweetening value of beet compared

with cane sugar is as 12 to 14, yet the advantages to be gained by Great Britain are so great that every effort should be made to foster the industry, and to do so protective duties, or an equivalent bounty, must be provided. Once the industrial principle be admitted—namely, that it is a duty of the whole people to see that the whole people shall be provided with opportunities to earn incomes adequate to civilised existence in decent comfort—then the governing powers will neglect no beneficent industry. They will add up the advantages to the nation, which are not always measurable in coin. The very expenditure, which is debited *in toto* by the political economist, is often of itself a cause of gain, deny it as he will. The mechanical instruction, the chemical practice and experiment, the example already mentioned and the industrial experience gained—applicable and often applied to other forms of production—are imponderabilia which the political economist omits from his estimates. There is one quality which we manufacturers, in common with all business men, value perhaps more highly than any other—perception. The possessor of it may be a lazy fellow, like the boy Potter, who invented the slide-valve, yet we are glad to buy or hire it. That is what each industrial development brings in its train—cultivated acuteness. To beet-sugar production and all else the same observations apply. You cannot instal a new industry without helping many others.

But contracts are now being offered in Mincing Lane for German sugar—so says "the trade"—for delivery when peace is declared. Are we going to allow business to the extent of £15,000,000 a year to leave the British Empire, as before the war, to strengthen quondam enemies? Yet powerful co-operative bodies are suggesting this, who are themselves large purchasers. As prices will be much higher, so the fifteen will swell to twenty millions sterling.

No Zollverein Possible.

Whether the country be large like Canada or Australia, populous as Great Britain, or smaller like New Zealand, the West Indies or the Falkland Islands, the ruling powers will make their own separate fiscal arrangements to a certainty. It is chimerical to suppose that there can be arranged a Customs Union—a Zollverein, as our Free Trade friends so love the German word. In twenty years it would be impossible to start such a convention, and its failure were inevitable. Free Preference is, however, not only assured, but it is a fact of existence. The Political Economists thundered at us who consistently fought the battle for sense and right—*sensus communis* in its highest meaning—that if we succeeded we should break up the Empire. Free imports alone, said they, would ward off war and win for our nation universal love and respect. We behold the result!

Britain followed out the folly to its bitter end. The eager affection of her Oversea sons counted for no more, fiscally, than the malevolence or indifference of aliens.

At the very time when Britain was being lulled to sleep and her prophets and wise men scorned, Australia was steadily exerting herself to do her bit in providing both army and navy. The aim was to have within a few years 800,000 trained men, even partially trained, at call. From which fact alone it should be plain that the Oversea nations of the Empire will and must make their own fiscal imposts and arrangements. The influence of Lord Haldane and his fellow thinkers could not be allowed to dominate the perceptions of Oversea electors. Compliance could not be enforced, and thus agreement alone can operate.

Allied Preference in Basic Material.

Schemes of Imperial cohesion, plans for inter-state and for Allied preference, usually embrace only dealings with manufactured goods. In connection with these, concessions are to be made in one form or other by way of rebates in import duties. The method is important, even requisite, and has the merit of simplicity *plus* experience in practice. But the very heart of the subject is elsewhere placed.

Sheep and Wool.

The supply of materials—constantly but wrongly called raw materials—is basic to all manufacturing industry. Monopolists know all about that, but serenely say nothing. They only ask for *laissez-faire*—desire nothing more than to be tenderly let alone. But it behoves the Allies to unwind the tentacles of these octopods and, if the unwinding be too troublesome, to cut them.

A combine controls the meat industry of the United States, has spread its control to Argentina, and is making vigorous attempts upon Australia and New Zealand. It encounters grave difficulties in Australasia, yet its immense success in dollar-raking over America and Europe suggests that the same procedure is practicable for wool and hides.

The colossal aggregations of capital seeking wide engagement, consequent upon the great war and accumulated in America, could find no more ready and profitable employment unless we be alert to prevent our own enslavement. British companies with pastoral holdings in Australia—often of great extent—may individually sell out to an American combine. Separately and seriatim, Australian persons and companies may do the same, and the purchase-money be withdrawn, as it mostly would be. That is not gain but loss to Australia. The ever-augmenting profits will be transmitted abroad, whilst wages and working expenses would be paid alike in either case.

The number of sheep in any country varies greatly with the seasons, but we may reckon as follows: The principal wool-exporting countries are Australia, owning 85,000,000 sheep; New Zealand, 25,000,000; Argentina, 85,000,000; and South Africa, 27,000,000. Of these the only one tending to an increase of its flocks is South Africa. There are 20,000,000 less sheep in Australia to-day than twenty-five years ago. In my calculations I have taken three-year periods so as to correct divergences because of seasonal effects or of interruptions in shipping. Thus for 1901 I take the average of 1900, 1901, and 1902, or for 1912, the average of 1911, 1912 and 1913, that our guidance may be safe. Thus we see that in 1900 the wool exports (not production) of Australia were 540 million lb. weight, and for 1912, 800 million lb., or an increase of 50 per cent. The industry is inherently healthy, but trammelled by illiberal conditions that we need not here discuss. The wool exports of South Africa in the same dozen years have enlarged from 76 million lb. weight to 176 millions—much more than double. In the newly-extended dominion of the South African Union there is fair prospect of wide expansion in the pastoral industry. The fact that private enterprise has improved the capacity of the sheep in wool-bearing has nothing to do with the falling-off in numbers. That is attributable to political mismanagement, which is a history to itself. Meantime the demand for wool is stronger than ever, and must for a long time remain unsupplied. There is no trust, no control, no concerted arrangement among the producers themselves to carry over from one season to the next or to withhold supplies when foreigners conspire against the producers' interests.

The whole United States possess barely 50,000,000 sheep, and Canada only 2,000,000—an inadequate total for more than one hundred million people.

The production of Great Britain has been stationary for a dozen years.

No further demonstration is needed of the necessity for preferential treatment of the exportable yield of the Empire in favour of ourselves and our Allies, particularly when we reflect that the deficit in production of the best of all clothing material enlarges annually. It must continue to enlarge until the political treatment of the waste lands of Australia becomes more just or more generous.

Horned Cattle.

In relation to cattle, I need not burden you with the statistics which are before me, for it suffices that similar conditions prevail. The world faces meat shortage and again an enlarging deficit. With that fact both Americans and Germans are perfectly acquainted. Again, in this respect—possession of horned cattle—the United Kingdom is stationary for a dozen years. Canada and New Zealand show a small increase.

British India—assuming that the published figures are reliable—shows an increase from 85 to 112 millions in cattle over a stretch of years.

Hides and Skins.

Now, a significant tendency has been for the United States and Germany to derive in ever-increasing quantities from Imperial flocks and herds another basic material of vast importance—skins and hides. There is no effective substitute for leather, and prices continue to advance.

Jute.

Of this India is sole producer. The production has increased as follows: in 1900, 2,000,000 acres, with 1,200,000 tons; in 1914, 3½ million acres, with 1,900,000 tons. Here is an article under complete control wherewith to assist ourselves and our Allies.

Once more permit me to remind you that the items and figures adduced are not comprehensive but illustrative, else you could not see the wood for the trees.

Cocoa.

Reckoned in short tons of 2,000 lb., the exports of the producing countries of the Empire have been so augmented as to show, in 1900,

shipments of 29,000 tons, and in 1912, 90,000 tons.

But of all products the most remarkable progress is shown in

RUBBER,

which from 9 million lb. weight in 1900, advanced with steady and rapid increase to 96 million lb. in 1913. There are £95,000,000 of British capital invested in the rubber-producing industry, and our share of the world's supply is 92 per cent.—say, eleven times as much as that of the rest of the nations added together.

LEATHER.

Not merely of hides, skins and leather itself, but of invaluable tanwares—cutch, myrabolans, wattle-bark, hemlock, chrome—our Empire produces for all the world. Without the control of hides and skins from India Germany will be in a bad way. Well-informed Indian officials have told me, "We were running India for the benefit of Germany."

Ministers in Australia have long ago seriously considered the question of imposing export duties upon hides, in order to conserve the tanning trade—the Cinderella of industries. Bark of the Australian acacia is an important product of South Africa, and though its cultivation in Australia has been neglected, it is perhaps, all round, the most valuable of the tanwares.

COCONUT OIL.

The absence of its manufacture from England is due to the wilful choice of Englishmen to erect factories in Germany so as to extract it there. Perhaps it is merely to exemplify the high principles of political economy so to sink their capital in a foreign State, employing labour there, filling German steamers with imports and exports, supplying excellent food for man and beast—to the deprivation of Britain—and the best material for detergents. Perhaps it was merely *ubi aurum, ibi patria*—policy of economy, and the devil take the hindmost. Many of us who travelled in Germany were amused by the queer jumble of words that stared at us from countless hoardings and from hideous newspapers—"Sunlight Seife." It is up to England to see that her own farmers get the benefit of the oil-cake, the by-product grown in her own Oversea domains, and that her Allies get a share in it too. And it will be no waste of time to watch keenly the pacifist influence of the whole soap-boiling trade. It had an octopus power of absorption, but Germany has stuck in its throat.

From the examples cited will be readily seen our power to benefit both Empire and Allies by ordered co-operation. Illustrations could be multiplied *ad libitum*, especially by including the whole range of metals and minerals excepting potash. The latter can also be found if systematically sought for.

THE WAR AS SCHOOLMASTER.

Fas est et ab hoste doceri. Before me are a number of copies of the *Kölnische Zeitung*, and it is not only a fair thing, but a very necessary thing, to be taught by our enemy. At least, it is wise to acquire knowledge of what he is teaching his own people. It is sure to come in handy later on, and the ostrich attitude will not help us at all. We dare not ignore the psychology of the Germans. The same man will be lachrymose one minute and savage the next. He will be querulous and critical, then obedient as a child to superior authority. He can be kindly and cruel, suspicious and credulous. Obsequious to servility, he will tell you stories of his multitudinous rulers and royalties, as also of their ancestors, that would put Suetonius and Macrobius to blushes. Such works as those of Clausewitz and Treitschke could not be written by a Frenchman. No Englishman could produce Krafft Ebing's awful "Psychopathia Sexualis." So, too, with the daily press. It is, of course, for Germans, and its leading matter is of late a long-drawn whine alternating with coarse boastfulness. I translate some extracts:—

"The war," says the *Cologne Gazette*, "burst upon us as the consequence of a deliberate policy, which is provable by documents, carefully devised for the encircling and suppressing of Germany, the undermining and destruction of Austria and the partition of Turkey. It was based upon the hope that the numerical superiority of the forces of the Entente, which had itself been reformed and enlarged, would find internal support and help from party oppositions in Germany, from national animosities in Austria-Hungary, and from weakness of Turkey, towards the subjugation of Germany and her allies. The declarations of our enemies prove that their war aim is permanently to weaken ourselves and our associates, so that we, in contrast with the aspirations of England, France and Russia towards a world-embracing policy and control, shall be condemned henceforth to the position of a State of secondary rank. We are to be forced into a condition of chronic anæmia in the domain of world-policy. The partition on the planet of dominions and spheres

of influence, together with the exploitation of the world's markets, is as far as possible to be completed without us. That they still, even now, hope to attain their goal, and that, if they gain the upper hand, they will carry out this programme restlessly and ruthlessly, our enemies leave us no room to doubt." The conclusion, drawn at too great length for full quotation, is that a peace must be forced through first of all, in which the pledges, the forfeits, that Germany has won from her foes, and will hold at her absolute disposal, shall procure such terms as will secure her position hereafter, for her war aims never included the idea of making conquests, as has been the invariable practice—so declares the veracious *Gazette*—of England. Another number contains an illuminating article upon :—

"England's Strongest Weapon—the Press."

"Its excellent cable service," says the *Kölnische Zeitung*, "in all parts of the world is a powerful weapon of the State, and ever since the outbreak of war has only too well proved itself as such. More even than the technical does the intellectual rule in its handiwork, guided by unswerving power of will and by long experience. In the leading articles of the English daily press during the war a great art is manifested in dealing with the separate nations according to their idiosyncrasies (*die einzelnen Völker nach ihrer Eigenart zu behandeln*), at one moment to strike the chords with severity, the next with brutality, then again with flattery, just as they hope to win success. Others again must be won by surprise-attack or by simulated probity." Then follows a column of abuse more amusing than instructive.

International Fairs.

But the same paper affords us a valuable finger-post in its report of Dr. Stresemann's speech in the Reichstag upon the question of the Leipzig Fair. Deputy Carstens had said :—

"The importance of the Leipzig Fair for our trade, our industry, and our workpeople is proverbial. Every possible effort must be directed towards maintaining the Leipzig Fair in its present importance. Germany, her trade and industry, her technical schools and her science, will constantly take care that the Leipzig Fair shall never be conquered. In view of the exertions of our enemies to continue a trade war even after the war, we must place all means in the hands of the Government, so that it may oppose successfully all assaults upon German industrial life."

Agreeing with the foregoing, Stresemann said, *inter alia* :—

"I am of the opinion that the proposal for State assistance to the Leipzig Fair is the obvious reply to the efforts of our antagonists to continue an economic war against Germany after the war. And just here in the Leipzig Fair we have the possibility of giving an answer to them. Even during the present war France, as well as England, has attempted to break through the old world-monopoly (*das alte Weltmonopol*) which the Leipzig Fair has won for itself through its conspicuous accomplishments in connection with the quality of German goods. England, which was formerly not only the land of Free Trade, but also in so far the land of free competition, as it almost never placed any State means at disposal for the support of industrial efforts (*wirthschaftlichen Bestrebungen*) has now, according to the information received, voted no less than £700,000 to create in Liverpool a counterpoise to the Leipzig Fair. France has applied herself to creating in Paris a fair for tobacco goods, for toys, and for furs. Under the leadership of the very active Mayor of Lyons, Monsieur Henriot, the attempt has also been made to call into existence a great fair as a counterpoise to Leipzig."

Deputy Schiele, of the Conservative party, said :—

"The Leipzig Fair is a concern for the whole nation. We shall not recover after the war even economically the *status quo ante*. Therefore everything must be done to reconquer the foreign market in behoof of our working-class. The late Ludwig Frank said that if we do not win the war, both in the military and the economic field, we must export men instead of merchandise. This Leipzig proposal is merely the introduction for other endeavours in furtherance of German export trade."

Dr. Bell, of Essen, said :—

"Even during the war everything must be done in the interests of our export trade. If after the conclusion of peace our enemies want to continue the trade war, we must stand up industrially armed. The watchword must be, 'Hereafter, as before, let the Leipzig Fair lead the world!'"

Allied Exhibitions.

At the risk of wearying you, it seemed well to point again to the wisdom of holding international fairs in the countries of the Allies, in other words, exhibitions which shall be professedly glorified shops, where only goods may be shown for sale purposes directly or indirectly. On that basis the whole public will

be interested, and every fair should be a financial success towards further and finer displays. And the exhibits should be limited to the Allies, so as effectually to assist in recuperating our injured fortunes. Even if the American eagle should scream, for once never mind him, but do all that is fair and lawful to help ourselves and help our friends. If we do not follow out such a policy, the glorious Alliance will fall apart—as the Germans confidently prophesy—and new associations of the Powers will be formed, to this Empire's imminent peril. This is not the last of wars; men will still be men; evil will persist in the world; avarice and luxury will again bring chastisement upon nations; peace, wealth and ease will form no guaranty for love, honour and purity. Our worst foes will be those of our household who will talk disarmament and dazzle our eyes with the films of Utopia.

Professor Muth, of Munich, whose name in German signifies "courage," published, in an intellectual serial, *Die Süddeutschen Monatshefte*, the text of a remarkable paper by Vincento Ludoslavski, a Polish writer, in which he declared that the British Empire has hitherto carried out and is still fulfilling a glorious mission in the earth. "Because," he said, "it was not built up by man, but is the handiwork of God—it can never be destroyed by man." There, then, is our trust as set forth, not by our own lips, but by another's, and as fiduciaries and without predilections it is for us to maintain the august heritage. It is not ours for ease and sport and pleasure alone, but to be carried on with regard to our awful responsibility. Then, indeed, will it be secure and, not without imperfections, remain the most beneficent creation of human genius.

"Economic Life after the War"
("*Das Wirthschaftsleben nach dem Kriege*").

I translate from the *Frankfürter Zeitung* of last month part of a private telegram which gives extracts from a speech of the Director of the German Grain-purchasing Department, Under-Secretary of State Michaelis. It was given in the Berlin University and was upon the "Providing of Bread-grain for the German People." After speaking hopefully of the present outlook for supplies, counting upon Rumania, he dealt with future prospects.

He distinguished the period of transition after conclusion of peace from the further future. This, let me remind you, is from a proved and able business man. In close translation the article runs:—

"For the transition period, which Michaelis reckoned to last for several years, he declared it to be indispensable that the Imperial Grain Office, as also the commandeering and rationing, must remain. It would be a wrong idea that with the declaration of peace the food-troubles would be at an end, and that across the wide-opened frontiers all would pour in that we are now lacking. The adjoining countries, as well the enemy as the neutral, find things as bad as we do, and they also will be just as slow to recover. Even America now threatens export prohibitions. Our agriculture has become poorer through want of nitrogen. We must therefore reckon, says Michaelis, that we must manage for years to come with our own production. Relief will begin firstly with the reduced demands for the army and from the conquered domains, which will be at our disposition for the provisioning of Germany with grain. But such improvement will only enter gradually, and it is wrong to clamour 'Give us peace, give us bread!' By the conclusion of peace the food-troubles will not be immediately lessened.

"Whether in the further future"—the Minister continues—"by utilising our experiences in the years of war and of transition, the control of home-grown grain or of that imported from abroad shall be taken over and dealt with by the State, is still an open question. But people must accustom themselves to the thought that after concluded peace the expenses of the German Empire will be quadrupled, if not indeed multiplied five-fold. Under the enormous pressure which the deterioration of our public economy, and at the same time of our individual husbandry has evoked, we shall be necessitated, for the restoration of ordered industrial life, to accustom ourselves to ideas which without this need and stress we should wholly reject. In this sense the war will prove, especially after its close, to be a stern schoolmaster."

Equally striking revelation of the radically hopeless position of the Germanic Empires is made in the Reichstag debates upon the food supplies, but to a commercial man like myself the most illuminating glimpses are obtained in the market and company reports. The subject is far too wide to enter upon, though intimately related to industry after the war. The deduction for us is to support in all conceivable ways our nation and Government in their efforts to raise promptly to a maximum the concentration

of energy. Above all things, to assist and insist upon tightening of the blockade. To weaken the enemy is nothing else or less than to win battles. To that end, therefore, squash our own *soi-disant* pacifists by any and every means, for out of their malevolent activities, were they successful, would assuredly come a renewal of the bloody conflict in still more awful form. As before said, we shall either end or extend the trouble.

Enemy Clothing.

Instantly, when war broke out, Australasia forbade export of wool and meat. Worse than lack of food is lack of clothing, for the former is remediable, but the latter is, in the military aspect, hopeless deprivation. All possible alertness could not save the enemy. He thought to find other fibres, and made experiments with nettles. I find from his own papers that the whole stock derivable, after concentrated scientific effort, and employing, according to the *Frankfurter Zeitung* of December 5th, 12,000 people in all parts of the Empire, amounts to 1,650 tons of dried nettle-stalks up to that date. Say with a yield of one-fourth actual fibre, the result is about 400 tons. Obviously an amateurish and unpractical scheme. The fibre is useful in peace time, but for uniforms inapplicable, because it will not stand strain and exposure. Repeatedly I find allusion to the spinning of artificial silk—a celluloid preparation —and of paper, no doubt a form of Kraftpapier; both useful enough ordinarily, but again inapplicable for military purposes.

To placate America in the traditional way, indirect deliveries of cotton to our enemy were permitted by us upon a vast scale after the start of hostilities. The effect was to raise his strength and hope, as also to raise immensely the cost of cotton to the Allies. After the war the Allies, in continued alliance, will be big enough and strong enough to take independent action commercially in their own behoof, and to consider their common interests in preference to those of dollar-chasing neutrals.

Foreign Domination.

America controls five-sixths of the entire tobacco selling trade of the British Empire. A single man, resident in Long Island, New York, possesses nineteen-twentieths of the sewing-machine manufacturing and selling of this Empire, owning not less than 60,000 branch establishments throughout the world. That is the apotheosis of capitalism and *laissez-faire*; but it is not in or for our interests. Is it even necessary to say so? Yes, and to say it a thousand times until attention be paid to it. For there is now in practice and further preparation by Chicago monopolists a comprehensive scheme to obtain monopoly of meat production and sale within the Empire *per fas et nefas*. Your neck is in the noose now, and your hopes are far more with the action of the Dominion parliaments than with the unwieldy British legislature hampered and hide-bound with scholastic tradition.

A Parliament of 670 members means an attempt to govern by public meeting. Dealing with the tangled controversy of Ireland has been its chief occupation, as well as the basis for the choice of its members, so long as I can recollect. Yet Ireland has fewer inhabitants than Australia or Canada, and not a tithe of the importance of either.

Arguments favouring the creation of a Parliament of the Empire have been often and amply refuted. The rejection of the necessary referenda by any of the States would be too disconcerting an outcome to justify the risk. History indicates other, sounder, and safer expedients.

It is a sure thing that our Allies will gladly help in keeping the respective domains of the several States—those of the ten Allies—from foreign domination and undesired exploitation. Or, on the other hand—limiting ourselves to the British Empire—if the Imperial Parliament would sweep away and keep away the foreign octopus of monopoly, whilst Canadians and Australasians were handed over Sinn Fein to deal with in its next outbreak, there would be "something doing." That is but a beautiful dream.

Cable and Aerial Messages.

Recalling the German tribute to our superb system of world-cables, why should we not offer freely to our fighting friends a preference in its use? What about grappling them to our soul with hooks of steel, or are we to drop them where they are, merely to placate the neutrals that did nothing for us anyway, unless it be a favour to sell us commonplace stuff at outrageous prices? It would greatly help our interstate commerce and Imperial progress if there were duplication and expansion of the services, so as to carry messages at low and unremunerative rates. Profit and increased interchange would follow.

Monopolies of Invention.

That channel through which aggregated foreign capital can and does exert an overwhelming force, in exploitation of mankind's energies, is popularly called "patents." The familiar word has been so distorted from its proper use as to be almost exclusively applied to authorised monopolies. The Associated Chambers of Manufacture of Australia specifically and spontaneously appointed me as their spokesman in London, and upon their behalf I am entitled to say that this subject of monopolies has not only caused them great concern, but has been the cause of repeated representations to the Commonwealth Government. The industries of the Empire suffer severely all the time from restrictions and imposts by foreign monopolists. Purchased often from British and Colonial inventors at low prices or insignificant royalties, the people of this Empire are bled secretly but surely to an incredible extent, and disadvantaged in many ways, by these monopolies.

Chiefly by litigation at enormous cost, thus terrifying recalcitrants, American holders of monopolies in shoe-making machinery particularly, renewing and extending their control by extremely clever manipulation, extract really royal revenues from the British Empire. This is unknown to all but those users who primarily pay the exactions.

The whole incandescent light industry was held in duress by an Austrian monopolist, who, by daringly vague but therefore comprehensive patents of monopoly, derived power for further exploitation. To fight his claims to monopoly of the use of a range of natural agents was proved to be ruinous. He lavished money upon the costliest legal advice and litigation, winning all along the line. The British public does not want monopolies, but its lawyers do. When the subject of these patents of monopoly comes up, in the course of years, before the Council of Dominions of the Empire, there will be a hope of remedy. Probably not till then.

The German Octopus.

After Armageddon you will have to deal with an industry in which the European nations have hitherto been most diligent, and for whose termination the soul of mankind prays with an inexpressible longing. That is the practice of setting up German kings, kinglets and princes to rule over the lives, liberties, and hopes of harmless nations. In that business we British have assumed a ghastly pre-eminence, and truly the Hohenzollerns owed us an everlasting gratitude. Let anyone take the "Almanach de Gotha," issued by Julius Perthes of Gotha; the German publication selected by our authorities and censors for untrammelled circulation in our midst. Let him take that mine of information and dissect it upon a pack of ledger-cards, firstly setting aside all prepossessions. Let him study and compare as I have done, and he will learn what the alleged "*Dei gratia*"—the "Grace of God"—has done for him and for hapless mankind. Let him plot out on the map of Europe the details of German interpenetration, and ask himself—himself alone—if he would assist in spreading the industry to France?

In 1870, the ostensible cause of the Franco-German War was the resolve of Prussia to place a prince of Hohenzollern to rule over Spain as first War-Lord. The announced desire of our own rulers was "to see a strong Prussia," and they realised it, although poor, broken, humiliated France saved us from the Spanish danger. Does anyone believe that a real democracy—as the United States, Britain, or France—could design and carry out preparations for world hegemony? Would anyone of those peoples submit to an order from above, "You mind your shops and factories, and leave the war business to us"? We are paying in blood and tears for our distrust of humanity in permitting—and even forcing—other nations to submit to the imposition of German princes, and thus virtually instituting in potency a restoration of the Holy Roman Empire that was neither holy nor Roman. The mild rule of the real Cæsars, however unworthy some of the successors of the great Augustus, was founded on the principle of allowing democracies to govern themselves, and it brought a peace to the world over greater area and longer duration than it ever knew before or has ever known since.

Knowledge Wanted.

The same Julius Perthes of Gotha is publishing by authority a series of books setting forth the ways and means whereby Germany is to regain her position of trade control and manufacturing dominance when peace shall come. To this, as so often herein insisted, the *conditio sine quâ non* must be German control of materials, especially within the British Empire. I have anxiously tried to get those books, but am told that the Censor has issued orders that no such books may be procured from Germany. Not too many of us who are versed in manufacture

and production—as well as representatives of producers' organisations—are also conversant with the German language, German mercantile practice, and exchange. The British Board of Trade—I am able to say authoritatively upon behalf of Australian manufacturers at the least —does not begin to fill the gap. We greatly prefer unfiltered knowledge gathered by ourselves, for what the Board of Trade offers us we seldom want, and what we want we seldom or never get. Consequently, we rely upon ourselves and our organisations to acquire the needful guidance. Hitherto we have found self-reliance count for a good deal, whilst there is an increasing generosity in the interchange, amongst producers, of specialised knowledge.

We shall have to compete with the German, and badly want to know what cards he holds, inasmuch as he assuredly—through his Censor—blocks nothing at all that can guide him.

A Request from Australia.

In 1914 a request was sent to the British Board of Trade from the Associated Chambers of Manufacture of Australia, desiring that effort should be encouraged to form an Association in Britain specifically to represent the whole body of British home manufacturers. It was hoped that it might take the same place in the United Kingdom as the National Manufacturers' Association of Canada in the latter country, or as a similar body in the United States. An answer was returned that the Board did not consider such a movement would serve any useful purpose.

It was, of course, a severe rebuff, and as certainly undeserved, for the sole aim was conservation of British energy by mutual help in the furtherance of industry. It has always been felt by industrials in Australia that their activities were looked upon askance by one of the great political parties of England. The manufacturers of Australia employ 350,000 people, and produce in the year goods to the value of £166,000,000. Even the added value to the materials exceeds the total value of any other department of production. And to tell these citizens, possessed of boundless goodwill, that their proposal of friendly association with their colleagues in Britain would serve no good purpose demands an adjective which I leave to others to supply. The mistake, however, was in applying to the Board of Trade at all. National movements are best promoted outside of officialdom, and so good progress in the desired direction has already been made.

I have not adduced in detail illustrations of Allied interchange and preference in the basic domain of metals, for the reason that I have undertaken to do so at some length next week in another place. It suffices that we possess a power of control to an extent that should fulfil all desires.

To sum up. The British Empire possesses sources supplying manufacturing materials of which some are of basic importance and at the same time unique. Our foremost duty is so to continue to ally ourselves with our Allies in this life-struggle as to help them faithfully and materially in the long and arduous process of recovery and restoration. We can best do so by preferring them in the supply of materials of all kinds. It is an unproved assumption that our enemies will pay us better prices than our friends. Again, we shall secure for the latter, as for ourselves, outlets for manufactures. And all that, even if in so doing we refuse again to permit Germany to monopolise or share in control of Australian lead, zinc and copper, or to absorb so much as she formerly did of the small remaining deposits of English china-clay; or to purchase again English coal-mines.

Means of Control.

The whole commerce of a country is compelled to pass through one valve—the Customs. Whether exports or imports, free or dutiable, everything is thus subjected to registration and control.

By operating this valve—which is by no means solely for ensuring collection of duties—foreign frauds and deceptions upon the citizens are prevented, objectionable goods are excluded, and preference is given to the Mother and sister countries. So, too, in many British States, export duties are received, control exercised over the issue of their own products, and all requisite statistics obtained. It becomes merely a question for solution by the wisdom of each Parliament how far to extend the principle of present action. We have already the way, we need only the will.

To conclude. The only security for existence, with freedom of the smaller nations, is that the Grand Alliance shall continue. You cannot trust merely to a "scrap of paper." To prevent outrages that are remediable only by a deluge of blood, there must be an irresistible confraternity of nations. America is a chaos of unassimilated peoples whose future no one can forecast. It is neither a race nor a nation, blink the fact as we may.

Europe's liberties are in her own keeping. The security for them is by genuine brotherly preference in every thinkable way, beginning with national business alliances based upon this voluntary preference as distinguished from bargains of any kind. Trust the people, trust the peoples, all the time. You have to depend upon their sense of honour in the last resort. Put not your faith in German princes, but insist upon their eradication as the *fons et origo mali.* From the limits of the habitable globe it is the man of the people, of ten nations and of countless races, who rushed to the bloody crusade for Christ and Right:—

"You took the Cross, although you didn't show it,
'Twas graven on a heart and not a shield;
'Twas for the Cross, although you didn't know it,
You mocked the horrors of the blood-stained field.

"You were but one, there was a host of others
Who felt full manhood when the trumpets blew;
Unconsciously you felt they were your brothers,
Nor knew that God was calling them and you.

"I mean you didn't hear the voices calling,
You simply followed where the Spirit led,
And when you saw them all around you falling,
You didn't know it was for Christ they bled.

"Duty impelled you and you never faltered—
There was no need for her to whisper twice;
The end you saw not—no, nor would have altered:
You took the Cross and made the sacrifice!"

DISCUSSION.

Mr. C. Sandbach Parker, member of the West India Committee and Chairman of the British Empire Producers Organisation, said that those who sat with the author on the executive committee of the British Producers Organisation had the privilege of knowing better than some of those present did before, his views on many of the questions that had been raised in the paper. He thought it would be agreed that the paper had shed a searching light on the manner in which these matters should be treated in the future; certainly they had hitherto not been treated as they ought to have been in many places, including one place not far away. The British Empire Producers Organisation, which had been referred to in the paper, was endeavouring to organise the industries of the Empire with a view to carrying out the objects to which attention had been drawn, and if they could, without Government interference and with Government help, succeed in bringing about a change of feeling in this country, and a closer relation in the future organisation of trade between Great Britain and first of all with our great Dominions and Colonies, and next with our Allies, a work would have been accomplished which would leave its mark on generations to come. Mr. Beale had mentioned some of the many articles that were under German control before the war, and he (the speaker) had had experience with regard to one of them, sugar. It was in 1884 when they in the West Indies were being utterly ruined by the policy of this country, because they were absolutely prevented from coming to an agreement with the United States who desired West Indian sugar for their people, on the ground that it interfered with that well-known fetish, the most favoured nation clause. Not only were they turned out of their own country, but they were prevented from making arrangements with another country who wanted their sugar. There were scores of other cases in which the same policy had been adopted, and the German control of metals was an outstanding example. We had had our eyes opened since the war started, because even those who thought they knew the extent of the German control had not the least idea of the extent to which it had penetrated, not only in the region of industry but in the region of finance. The lesson of the war was that those of us who were not able to fight at the front for our country ought at home to see that the reward of the efforts of those who did was not lost. We must put our industry in such a state that after the war it would be possible to benefit the children and the grandchildren of those brave men who had laid down their lives for us.

Colonel C. E. Yate, C.S.I., C.M.G., M.P., said that although neither a producer nor a manufacturer, he had listened with joy as an ardent advocate of Imperial preference, to the paper. Mr. Beale had been appointed specially by the Australian Associated Chambers of Manufacture as their spokesman in this country, and they would all agree that Australia had made an excellent choice. The fact that the Australian people were now getting for 3*d.* sugar which costs 6*d.* in England was a justification of the policy which Mr. Beale advocated. If we had only had a protective duty years ago to foster the sugar-beet industry we should not have been in the position in which we were now. A new policy, he was glad to say, had recently been instituted, by which the Colonial Secretary had been empowered to put a tax on exports to foreign countries of palm kernels which were a monopoly in West Africa, and he hoped that jute and other monopolies in the British Empire would be treated in the same way. If anyone wished to know more about jute they should read the paper read last session before the Indian Section of the Society. As an old Indian officer he thoroughly endorsed what Mr. Beale had said about the German control of hides and

skins from India, and he fully appreciated the remarks made by the well-informed Indian officials, "We were running India for the benefit of Germany." He also appreciated the remarks in the paper about the Board of Trade, to the effect that "What the Board of Trade offers us we seldom want, and what we want we seldom or never get." He had seen the answer in connection with the request from the Associated Chambers of Manufacture of Australia regarding the formation of an association in Britain, viz. that "the Board did not consider such a movement would serve any useful purpose," given many times in connection with other matters, and realised the utter hopelessness of such a point of view. He hoped the policy recommended by Mr. Beale would come to early fruition as the result of the war.

MR. C. R. ENOCH remarked that the point to be borne in mind in connection with Imperial industries after the war was how to develop the enormous resources of the Empire so that they would be of benefit to the bulk of the people. Whilst we must trust the people we must also feed the people. Could it be done by State organisation, and should we in that way get more sugar, cocoa, fats, oils and other commodities from our Colonies, and he would specially mention the Crown and tropical colonies, or would private organisation be the best means? He believed that Imperial preference would accomplish a great deal, but we should have to go still further and see how we could get into closer touch with the enormous properties of the British Empire.

THE CHAIRMAN (the Rt. Hon. Sir Joseph Ward, Bt., K.C.M.G.), in moving a vote of thanks to the author of the paper, mentioned that he had received a letter of regret at his inability to be present from Sir Cornthwaite Rason, who also expressed his deep sympathy with Mr. Long in his terrible loss. With regard to the paper it was obvious that it could only have come from a very fruitful brain. Mr. Beale was diffusing the great feelings of dissatisfaction felt by the great proportion of the people in the Overseas Dominions—and to a large extent now by people in this country—with the pre-war conditions under which our enemy was making tremendous advances all over the Empire. In New Zealand preliminary steps had been taken to bring about a change, and he himself had put a clause into a Bill last session—it was now an Act of Parliament—under which, the moment peace was declared, an extra 50 per cent. duty would be placed automatically on all imports from an enemy country.

The vote of thanks was put to the meeting and carried unanimously.

MR. BEALE, in reply, said the only point that called for immediate comment by him was the remark of Mr. Enoch as to how we should develop the great resources of the Empire for the benefit of the whole of the people. There could not be a better man to answer that question than Sir Joseph Ward himself, because when he was in New Zealand he taught us from observation, imitation, and experiment how to make the most of the Empire's resources. If there were awkward experiments they had the courage in New Zealand to try them, and what was more they made them successful. If that example were copied throughout the Empire the whole object he had tried to explain would be attained. One instance of the good example set by New Zealand was when Sir Joseph Ward was Treasurer out there at the time differential duties were imposed which were to give a preference to Great Britain. As a mercantile man observing such matters, he was entitled to say that it was done with really remarkable skill. For instance, cement was an article heavily exported from Germany, it being used to give "stiffening" to German vessels trading with Australasia. The general range of duties was 50 per cent. higher against foreign competitors, but they put a double duty on cement, and he could safely say it was meant to hit German cement. At the other end of the world, at all events, they always looked on Germany as their potential enemy, and neither Mr. Enoch nor anybody else could have any idea of the consternation and even anger in the Overseas Dominions when Germany was granted a slice of New Guinea to enable her to set up a naval establishment and threaten, if not dominate, the southern seas.

MR. G. WILSON, C.B., on behalf of the Committee of the Colonial Section, thanked Sir Joseph Ward for taking the chair.

TENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 14th, 1917; The RIGHT HON. LORD FARRER in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bertrand, J. F., Isle Verte, Temiscouata County, Quebec, Canada.

Chrimes, Thomas Edward, R.N.A.S., Holmcroft, Wilbury Villas, Hove, Sussex.

Comber, Joseph Forstall, Assoc.Inst.C.E., The Lagunas Syndicate, Ltd., Oficina North Lagunas, Iquique, Chile.

Eckford, Captain George, R.E., The Old House, Milston, Salisbury.

Lewis, Nolan D. C., M.D., Crownsville State Hospital, Crownsville, Maryland, U.S.A.

Loring, Mrs. William Caleb, 2, Gloucester-street (corner of Beacon-street), Boston, Massachusetts, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Chellew, George, 99, Chevening-road, Willesden, N.W.

Davis, William Alfred, Pusa, Bihar, India.

Rodd, Captain William James Paulo, A.O.D., c/o Sir Charles R. McGrigor, Bt., and Co., 39, Panton-street, Haymarket, S.W.

Stone, Judge Kimbrough, Kansas City, Mo., U.S.A.

THE CHAIRMAN, in opening the meeting, read the following letter from Lord Eversley, the veteran Chairman of the Commons and Footpaths Preservation Society:—"I very much regret that I am unable in this inclement weather and at my age to go to London for the purpose of being present at the meeting of the Society of Arts, when Mr. Lawrence Chubb will read his paper on "Highways and Byways." I have not read his paper; but I feel very certain that I shall agree with all he says on the subject, for no one knows better than he does the difficulties which arise when the public desires to assert its rights." He had also received a letter of apology for inability to attend the meeting from Lord Weardale. Everyone was interested nowadays in the subject of highways. He knew it was said that *inter arma silent leges*, but still they had had such experience lately of the importance of means of communication that the history of them ought to be exceedingly interesting. Now that railway travelling had to be given up from patriotic motives, more use would be made of highways and footpaths, and to keep the footpaths open appeared to him to be one of the primary conditions of the happy civilisation under which English people had lived for so many years.

The paper read was—

HIGHWAYS AND BYWAYS.

By LAWRENCE W. CHUBB,
Secretary to the Commons and Footpaths Preservation Society.

The story of the King's highway has the rare merit of being able to arouse the interest and quicken the imagination of all sections of the community. It appeals to the historian and to the student of sociology, because each great era of road construction or improvement in this country has synchronised with vital changes in the social life and environment of the people and in the economic development of the land. It was, for instance, due to the vast network of roads constructed during the period of Roman occupation that Britain was finally subjugated and the door was opened to the forces of civilisation as well as to the effective use of military power. Again, the coming of the Turnpike Trusts and "Macadam the Magician" contributed largely to the enormous expansion in industry and commerce which took place in the Georgian period. It will be the task of the future historian to appraise the services rendered by highways in these days when the fate of nations is in the melting-pot. In the meantime, none will deny that problems of vital importance in connection with the rapid transit of troops and supplies have only been rendered possible of solution by practical experience gained on highways in connection with the development of the motor-car.

The romantic and picturesque incidents associated with ancient and modern methods of travelling have, since the time of Chaucer, exercised a striking influence upon literature, and the subject of highways has, for mundane and other reasons, a great attraction for the lawyer and engineer. It makes its strongest appeal, however, to the imagination of the man in the street, for the word "highway" symbolises public rights and freedom—

"Fair and free, night and day,
Fair and free is the King's highway."

It is to this aspect of the subject that I desire mainly to draw attention because, while every individual is personally concerned in the preservation of highways, few realise the limitations of public rights and the difficulty of maintaining them, or appreciate the ceaseless and bitter struggle which the Commons and Footpaths Preservation Society has found it necessary to wage on their behalf in order that those rights may be maintained.

A public highway may be defined as a strip of land over which every subject of the King is lawfully entitled to pass. The extent of his rights is another matter. If he is merely entitled to passage on foot, the way is a highway for foot-passengers only; if he is entitled to ride a horse over a track, the way is a bridle-path or horseway, and a footpath as well. If carriages may lawfully be driven by the public over the way, it is a carriage road and also a bridle-path and footpath.

The public right is confined to an easement of passage; it does not embrace the ownership of the soil, which, in most instances, remains vested in the adjoining owner or owners by whom, in normal cases, is owned the freehold to the centre of the metalled portion of the carriage-way. That is why the timber growing on the open wastes at the sides of roads belongs to the adjoining owners. So jealously do the Courts preserve the landowner's interests that it has been held that a man is not entitled to walk

backwards and forwards along a public path over a Yorkshire moor in such a way as to interfere with a grouse drive (*Harrison* v. *Duke of Rutland* (1893), 1 Q.B. 142). In delivering judgment in this case, Lord Justice Lopes enunciated the legal principle involved. He said: "If a person uses the soil of the highway for any purposes other than that in respect of which the dedication was made and the easement acquired, he is a trespasser. The easement acquired by the public is a right to pass and repass at their pleasure for the purpose of legitimate travel, and the use of the soil for any other purpose, whether lawful or unlawful, is an infringement of the rights of the owner of the soil, who has, subject to this easement, precisely the same estate in the soil as he had previously to any easement being acquired by the public." In another case (*Hickman* v. *Maisey* (1900), 1 Q.B. 752) the defendant was held to be a trespasser because he walked backwards and forwards along a public carriage road in order to observe the form of horses under training on adjacent downland. In this case, however, Lord Justice Smith held out a crumb of comfort to the weary wayfarer, for he said: "If a man while using a highway for passage sat down for a time to rest himself by the side of the road, to call that a trespass would be unreasonable. Similarly, if a man took a sketch from the highway I should say that no reasonable person would treat that as an act of trespass." In another dispute (*Fielden* v. *Cox* (1906), 22 T.L.R. 411) the Court declined to grant an injunction to restrain persons from trespassing on a highway by using it for the purpose of catching moths by means of lamps and other appliances, on the ground that the trespasses were merely technical.

Nevertheless, the strict legal view is that a pedestrian is not entitled to a general right to stray over land not dedicated to the public use and enjoyment, although that land is unenclosed common or open down; and so accustomed are we to speak with pride of an Englishman's rights that it comes almost as a shock when we first realise that his most comprehensive right—a right of way—is confined within exceedingly narrow limits, and that it is possible that a man may be a trespasser upon a public highway.

Having thus considered the nature of a public highway, it becomes necessary to make some inquiry into the origin and history of such ways. Theoretically, every highway must have originated either by the operation of an Act of Parliament or by dedication—express or presumed—by some owner of the land over which it passes. Although, as we shall see, a number of carriage roads and fewer footpaths have been created by statutory authority, the vast majority are deemed to have come into existence by means of dedication. "Dedication" is the expression used to describe a convenient legal fiction devised to account for the existence of a public interest in highways. The word connotes the grant to the public, by some past or present freeholder, of a perpetual right of passage over his land. On rare occasions dedication may be proved by the production of an actual grant, or it may be implied by special acts clearly indicating the intention of the owner to give to the public an inalienable right of passage. This form of dedication is known as "express" dedication, but it is not often possible to establish it. All that can be proved in normal cases is that, throughout living memory, a path or road has been publicly used as a thoroughfare, freely, openly, and without interruption. Where this is possible it is presumed that dedication has taken place, although no actual grant can be produced.

It is obvious that the percentage of rights of way which have been dedicated in a literal sense must be infinitesimal, for few owners would be inclined voluntarily to burden their property with an easement which, once existing, could only be lawfully extinguished by Act of Parliament, or by an elaborate and expensive process involving a justices' certificate and the consent of Quarter Sessions, or by the utter destruction of the way through some act of God.

When it is remembered that the antiquity of highways in general cannot be gainsaid, the doctrine of presumed dedication, and all that it involves, appears to the lay mind to be not far removed from the ridiculous. Some deeply-scored by-roads in use to-day probably existed as foot-paths and pack-ways in the time of the early Britons for the conveyance of tin and furs in pre-Roman days. Yet each of them is deemed to have originated in dedication.

Before asking you to consider the difficulties which the public encounter in maintaining their rights of way in consequence of the far-reaching effect of the theory of dedication and all that it implies, it may be convenient that I should outline the origin and development of our highway system, and the manner in which ways have been created by Act of Parliament. We owe the foundation of that system to the

Romans. Those wonderful road-makers were worried by no problems with regard to dedication or the sacred rights of property, but drove their ways over hill and dale, through morasses and dense woodlands, with a relentless purpose and patient industry which we can only admire with amazement.

The main Roman roads certainly extended for an aggregate distance of 2,500 miles, and some scholars of repute believe that their total length in Britain amounted, with their connections, to over 4,500 miles. When it is remembered that the flint, gravel, and other material required for the high causeways on which the roads were formed sometimes had to be carried for great distances, it is possible to realise something of the marvellous achievement of the Romans.

The construction of important trunk roads must have led to the opening of many cross tracks, but there is no evidence of efforts to maintain any of the Roman roads after the departure of the legions. They endured in spite of neglect, because they were well built. Indeed, the four great routes, Watling Street, the Icknield Way, the Foss Way and Ermin Street, came to be regarded as of value for a reason quite unconnected with traffic. They gave the King's peace or sanctuary to any man who fled to them for succour. While on them he was safe from pursuit or molestation.

With the imposition of the rule of the Norman and the organisation of the manor as a unit of local government, the maintenance of the King's highway was imposed as a theoretical duty upon the lord of the manor and his tenants subject to the adjustment and control of the Court Leet. Wheeled traffic was almost unknown, save for the rough carts utilised to carry home the crops, and the customary highways were for centuries almost exclusively traversed by pedestrians and horsemen. Until the dawn of the nineteenth century the principal part of the corn in remote districts was conveyed to market by pack-horses, although in some places common carriers were prepared even in the fourteenth century to convey grain by cart at the rate of one penny per ton per mile.

The Statute of Winchester, passed in 1285, was the first Act of Parliament which purported to deal with roads. It did not go far, for it merely ordered that "highways leading from one market town to another shall be enlarged where as bushes, woods, or dykes be, so that there be neither dyke nor bush whereby a man may lurk to do hurt within 200 ft. of the one side and 200 ft. of the other side of the way." No attempt at actual maintenance of the surface of the highway was made, or was considered necessary, until the growth of vehicular traffic rendered repair an imperative necessity. If the way became foundrous or impassable, the traveller might deviate upon the adjoining land, even if cultivated, for the judges decided that it was "the good passage" that constituted the highway and not merely "the beaten track." Where the land on either side of a public way remains unenclosed this rule still obtains, and if fences are erected to separate the highway from the adjoining land the burden of repair, *primâ facie*, still falls on the adjoining occupier, as long as his fences debar the public from their common law right of deviation.

It was not until 1555 that another Highways Act was passed (The Mending of Highways Act, 2 & 3 Philip & Mary, cap. 8), and this once and for all cast upon the inhabitants the obligation to maintain the highways in their parish. Surveyors of highways were ordered to be appointed by the parishioners, and were authorised and required to direct the performance of statute labour upon the roads. This was a form of National Service which no man might lawfully evade, but which imposed a burden from which all endeavoured to screen themselves. Nevertheless, roads became more neglected than ever, and were monopolised by large droves of cattle, sheep and pigs; even flocks of geese slowly tramped their way along the muddy ways from Norfolk to the markets of London. Many new highways, too, came into existence with the passage of thousands of Acts authorising the inclosure of commons. The awards made in pursuance of the Acts directed the setting out of convenient ways, but the question of repair remained unsolved. Turnpike trusts were therefore devised to remedy the deplorable state of neglect into which the King's highway had fallen. Certain individuals, with a view to the repair of particular roads, subscribed among themselves for that purpose, and erected gates upon the roads, taking tolls from those who passed through them.

The first scheme of this kind received the consent of Parliament in 1663, and dealt with ways in Herts, Cambs, and Hunts. It was not, however, until 1706 that the first Turnpike Act proper was passed. This proved so successful that, altogether, over 1,100 turnpike trusts were created in England and Wales, having under their control 23,000 miles of road and enjoying and spending a gross annual revenue of £1,500,000. Each trust was empowered to

construct and maintain a specified piece of road and to levy tolls for a limited period, usually twenty-one years. The powers were renewed from time to time, and Parliament further permitted the Surveyor of Turnpike Trusts to require the performance on the roads under his charge of the unpopular and personal obligation of Statute Duty and Team Labour first sanctioned in 1555.

The friction caused by the erection of turnpikes and the imposition of tolls led to much disorder, and culminated in the notorious Rebecca Riots in South Wales. In the meantime, general Acts were passed authorising the punishment by whipping and, in 1734, even by death of offenders who destroyed gates or toll-houses; but the state of friction continued until Parliament adopted a recommendation of a Select Committee of the House of Commons made in 1864, and finally declined to renew Turnpike Continuance Bills. The Highways and Locomotives Act, 1878, provided that such roads should become main roads, the expense of repair being jointly defrayed by quarter sessions and by grants from the Consolidated Funds. These roads are now under the care of the county councils.

It is greatly to be regretted that, by an obvious oversight, Parliament, when abolishing turnpike trusts, did not take steps to ensure that their records should be handed over to quarter sessions. It was enacted that the special powers of the trusts to abate encroachments should be continued; but the plans and records of the trusts, which were essential to prove the existence of such encroachments, remained with private individuals to whom they were useless. Such records have a definite historic value, and should be in the keeping of the county authorities. They throw much light upon economic problems of the eighteenth and nineteenth centuries, and are of considerable public interest and utility. County councils should therefore be empowered to acquire these records, on the ground that they concern all the main highways in the country, many of which have been public roads since their construction by the Romans.

Time does not permit me to describe the gradual development of the civic responsibility for the maintenance and preservation of secondary and other highways. On this subject many Acts of Parliament have been passed; indeed, so numerous have these become that authoritative works of reference upon highway laws give extracts from over fifty. A great public service would be rendered if these Acts could be consolidated into one comprehensive Statute.

It may be permissible to express the hope that a group of the barristers who doubtless have recently volunteered for some form of National Service may be deputed to perform this practical and useful task.

Few of us, perhaps, realise the vast expenditure entailed in the upkeep of public roads in England and Wales. For the last normal year before the war it amounted to over ten and a half million pounds—a sum which considerably exceeds the total revenue of Denmark. The burden of repair is increasing rapidly. Since 1907 it has grown by 11½ per cent. The total length of roads repaired by local authorities already amounts to not less than 151,112 miles, and if, and when, the recently proposed schemes of arterial road construction materialise, to meet the growing needs of speedy motor traffic, it is clear that the State will have to bear a considerable share of the financial burden.

It is now necessary to invite you to consider what is perhaps the most important and interesting aspect of the subject—the protection of public rights of way from obstruction. We have seen that once a highway has been dedicated to the public it can only be lawfully closed by Act of Parliament or justices' order. To obstruct it by any other means is unlawful, for the obstruction of a public way is a nuisance. We are all familiar with the maxim, "Once a highway always a highway," which is based on a decision that no length of time can legalise a public nuisance (*Rex* v. *Cross*, 3 Camp. 227).

Theoretically, therefore, a highway of any kind once created can never be lawfully closed by the irregular action of any individual. This principle has held good for generations, but prior to the reform of local government effected by the Local Government Acts 1888 and 1894, the burden of protecting rights of way was not obligatory upon a local authority, but mainly depended upon the voluntary efforts of the village Hampden. The power of the cumulative vote enabled one or two owners to disregard the needs and wishes of the inhabitants of an entire parish in vestry assembled.

For many years the Commons and Footpaths Preservation Society had found it necessary to include in its programme the work of preserving public rights of way, and the National Footpath Preservation Society, formed in 1884 by the late Mr. Henry Allnutt, also did much useful work.

The need for outside action was great, espe-

cially in the neighbourhood of large towns. Footpaths were being closed on every hand. In the meantime, appreciation of the unspoilt beauty of our countryside was slowly spreading, a certain sign that people even in a material age, if given a fair chance of elevation, will rise above the sordid and unnatural conditions of city life. Rambling clubs came into being with the object of encouraging fieldpath walking. They were helped by many footpath guides, the most comprehensive of which were to be found in the invaluable series of "Field Path Rambles" issued by the late Mr. E. S. Taylor (Walker Miles). In the meantime, the Commons and Footpaths Preservation Society organised many branches, including special committees to watch over the counties of Kent and Surrey, and Middlesex, Herts, and Bucks. It was felt that such committees were needed, having regard to the extraordinary rapidity with which the Metropolis was stretching away into the green fields of the home counties, dotted with commons and covered with a network of footpaths which, in the picturesque simile of the late Miss Octavia Hill, made meadows, fields and woodlands one vast park open to all, until the hands of the builder actually descended upon them.

The deep human interest, shrewd commonsense, and practical sympathy and enthusiasm of Miss Hill were placed whole-heartedly at the service of the Society and its Kent and Surrey branch, and were assets of the utmost value to the work.

These county committees were most fortunate, too, in having as their first chairman the late Sir Robert Hunter, whose unique knowledge and experience of the intricacies of the law of commons and highways, together with his zeal for the cause of public rights, were of infinite service to the movement.

In 1899 the National Footpaths Preservation Society was amalgamated with the Commons Preservation Society, and the work has so grown that, during the last twenty years, nearly 10,000 cases of obstruction of public roads, bridle-ways, and footpaths have been dealt with by the Society. Relatively few of these cases have concerned public carriage roads. Those highways are generally repaired at the public expense and, when that has happened, no question can arise as to the existence of a right of way. Only a small minority of footpaths, however, are repaired by the public, and disputes with regard to them are of frequent occurrence.

It is, therefore, fortunate that local authorities have far-reaching powers which, if wisely and fearlessly employed, render difficult, if not impossible, unlawful attempts to obstruct rights of way. Lord Eversley, the veteran president of the Society—the monument of whose fifty-one years of devoted and successful service in fighting the people's battles may be seen in the tens of thousands of acres of common land over which all may wander at will—succeeded in securing the insertion in the Local Government Act, 1894, of a drastic clause (26) with regard to rights of way. This clause declares it to be the duty of district and town councils, as highway authorities, to maintain all public rights of way within their area or in an adjoining district. They were directed to take any steps necessary to that end, including legal proceedings. In rural districts the Act authorised the parish council or parish meeting to put the highway authority in motion, and if it evaded its obligatory duty a power of appeal from the parish to the county council was given. Local councils have, therefore, ample facilities for vindicating public rights, but, in practice, it has frequently happened that they have failed to act. The reasons for their inactivity are manifold. Sometimes they fear a lawsuit with its attendant expense, trouble, and uncertainty; or they may be composed of persons who have no sympathy with the public point of view. Again, in an even greater number of cases, they may be influenced by the fact that many of their members work for, or are tenants of, the landowner who is endeavouring to shut up a public path. The power of territorial influence in a country parish is very real. In one typical case in which the Commons and Footpaths Society succeeded in securing and re-opening a public path, the aggressor was not only a magistrate, the patron of the church living and the lord of the manor, but the chairman of the district and parish councils, and a county councillor as well. Naturally, none of those bodies would enforce the law against him; and in this, and in thousands of cases of a similar kind, it has only been the force of popular opinion created, organised, and crystallised into action by the Commons and Footpaths Preservation Society that has led to the vindication of public rights.

A footpath has many enemies, and it is fortunate that it is a stubborn thing. Its origin may be lost even to tradition, but the path pursues its way with odd twists and turns which now appear meaningless, but which, in former days, enabled the wayfarer to avoid morasses, ponds, trees, or other natural obstructions which

have long since disappeared. The path at one time probably led to a now-forgotten shrine or chapel or well, and it certainly came into use to meet a local need. At the moment it may be valued only by ramblers and nature study enthusiasts, but that affords no reason why it should be arbitrarily closed. The ebb is followed by the flow, and paths which to-day may be of little value in the utilitarian sense may to-morrow become of much importance, especially now that the motor-car absorbs the country lane as well as the great main roads.

When a right of passage over a path which has hitherto been open is challenged, the first step which must be taken is to ascertain and marshal the facts both for and against the popular claim. A public path has certain definite characteristics. As a rule, it is provided with stiles, wicket, or other gates and footbridges; it is often a short cut, and it must be a thoroughfare leading from and to a place where the public have a right to be. Above all, it is desirable to be able to prove that the path has, in fact, been used for a long time as a public way by all who have desired to traverse it. Records, such as tithe or inclosure awards, sale plans, or ancient maps may be available to prove the antiquity of the way, although in view of recent decisions many maps are not admissible as evidence unless the surveyor by whom they were made can be produced to prove them.

Unfortunately, up to the present, Parliament has prescribed no fixed period of years of user for establishing a public as distinguished from a private right of way. The period varies in accordance with the views of particular judges, and with all the circumstances in connection with the formation, location, and history of the path. In one metropolitan case (*North London Railway Company* v. *Islington Vestry* (1872), Q.B. 37, J.P. 341), the brief period of eighteen months' user was deemed to be sufficient to support the presumption of dedication. In others, as we shall see, evidence stretching back as far as the oldest men can recollect has been held to be inadequate. It is, therefore, desirable to aim at securing evidence of forty or, if possible, of sixty years' duration.

Assuming that inquiry has proved satisfactory upon these points, and that no adverse evidence has come to light, it is fairly safe to conclude that the path in question is, *prima facie*, a public right of way. But it must not be forgotten that, in the case of most ways which have been challenged, evidence of some sort is also available on the owner's side, and it is of extreme importance that this also should be ascertained. As we have seen, public paths were not created by user. They originated in dedication, and, save in the rare cases where "express" dedication is capable of proof, it is necessary to establish a chain of facts so strongly in favour of the public contention that a judge will hold that the only fair inference or presumption to draw from those facts is that some owner, at some time or another, intended to dedicate a right of way. Such an inference may manifestly be rebutted if the owner can produce evidence of steps taken to protect himself from the presumption of dedication. Sometimes he has erected and maintained notices clearly indicating that persons using the path have done so with his permission; at other times he has closed the path once a year; or, again, he may have issued permits for the use of the path. The owner may easily and fully protect himself by steps of this nature from the risk of having a revocable licence transformed into a right against himself.

But, as a rule, obstruction, like dedication, is a gradual process, and the form of obstruction most to be feared is of a surreptitious nature which affords an unscrupulous landowner many opportunities for building up a case against the public. His first step will probably be to discourage the use by his own tenants and employees of a path he seeks to close. A frequent excuse is that he wishes to establish game preserves and desires privacy. In a country village, where the cottages all belong to one owner, it is almost impossible for the tenant to ignore the wishes of his landlord. I have known instances in which a man has been summarily ejected from the home of his fathers because his conscience would not permit him to acquiesce in the unjustifiable and unlawful obstruction of a public path. Such landlords are, fortunately, few in number.

Another favourite device is to erect notice-boards warning trespassers or boldly denying the right of way. Sometimes notices are of a more intimidating nature. "Beware of the bull" is often met with; while near Uxbridge a fearsome notice warning pedestrians to "Beware of the Red Bloodhound" may be seen. Close to Croydon, too, there is a wood, happily crossed by several beautiful public paths, where notices warning pedestrians against mantraps and spring guns are still displayed, although the use of such barbarous engines has long been illegal.

These wooden falsehoods, as they have been aptly described, are difficult to overcome, for, as an eminent judge once said, "A man is entitled to erect on his own land as many lies as he likes, provided they are not libels." The best remedy for this form of attack is to urge the district council to erect finger-posts under the powers conferred upon them by the Highway Act, 1835.

Sometimes, too, the path is obliterated and rendered inconvenient by ploughing. The rule is that a path cannot be lawfully ploughed unless it was originally dedicated subject to the reservation by the owner of the right to plough. Proof of that reservation exists when the path has been regularly ploughed up in the ordinary course of husbandry in the past (*Harrison* v. *Danby*, 34 J.P. 759).

Another method is to place barbed wire at the sides of a path in such a manner that pedestrians using the way run the risk of injuring their persons or clothing. If the wire is, in fact, a danger it should be removed as a nuisance at the instance of the highway authority under the Barbed Wire Act, 1893, and damages for injury may be obtained (*Stewart* v. *Wright*, 9 Times L.R. 480).

Some persons do not hesitate to put bulls or other savage animals in a field through which a public path passes. They have no legal justification for action of this kind, and in one case (*Lowery* v. *Walker*, L.R. (1911), A.C. 10) the House of Lords decided that a man was entitled to damages for injuries inflicted by a horse while he was following a footpath not dedicated as a public right of way, but which was habitually used by the public to the knowledge of the owner as a short cut to the railway station.

Many a path, too, has been gradually lost because the stiles and gates are inconvenient or have been allowed to become defective; because footbridges or stepping-stones have disappeared, or because, for lack of a little attention, the tracks have become water-logged or overgrown.

It cannot be denied that a stile perched on the top of a bank may become a serious obstruction when footboards are removed, or when the whole structure decays.

It is not generally known that the poet Cowper evidently intended to add to his "Diverting History of John Gilpin" an account of Mrs. Gilpin's trials on a journey by footpath to Edmonton. The three stanzas which were found in the poet's handwriting may be quoted, as they describe the predicament of many pedestrians who have endeavoured to surmount an awkward stile:—

> Then Mrs. Gilpin sweetly said
> Unto her children three,
> "I'll clamber o'er this style so high,
> And you climb after me."
>
> But having climb'd unto the top
> She could no further go,
> But sate, to every passer-by
> A spectacle and show,
>
> Who said, "Your spouse and you this day
> Both show your horsemanship,
> And if you stay till he comes back,
> Your horse will need no whip."

It is, *prima facie*, the duty of district councils to repair all public highways (including footpaths, but not main roads) known to have been in existence before the Highway Act, 1835, became operative, unless the burden of repair, *ratione tenuræ* or *ratione clausuræ*, falls upon the occupier of the land through which such ways pass. The councils can and should keep public paths in a reasonable state of repair, and if stiles are allowed to degenerate into such a condition that they are a hindrance to passage they should be dealt with as obstructions. Parish councils, too, are entitled to repair footpaths which are not situate at the sides of public carriage roads, and the Local Government Board have decided that they may also repair stiles and gates, although, in a technical sense, such erections are part of a fence and not of the highway. As to the nature of the repairs the law holds an even balance. The council must not decrease the height of a stile or put a wicket gate in its place if the owner raises objection, because by so doing it would be encouraging a greater number of persons to use the way. On the other hand, the owner may neither make a stile less convenient nor erect one where none previously existed, because if he did so he would be diminishing the public right. In the latter event, too, he might interfere with perambulators, for it has been laid down that the homely perambulator may be wheeled over a footpath, provided it is not of such size and weight as to injure the soil or inconvenience pedestrians, the justification being that a perambulator is a usual accompaniment of a large class of foot-passengers (*R.* v. *Mathias* (1861), 2 F. and F. 570).

Field-paths are of so much advantage to the community that it should be the aim of every council to maintain those within their area in a reasonable condition. They must not, without consent, metal a path which has not previously

been repaired, or they may find themselves in the unenviable predicament recently experienced by a Berkshire parish council, which was served with a writ by an irate owner because it had innocently ventured to put down a little stone in holes in a meadow-path, in order to enable the village children to reach their school dry-shod. But they can, in practice, do all that is required to prevent a path from vanishing through disuse.

The public should be on their guard against the unauthorised diversion of rights of way. It sometimes happens that diversions are effected without a magistrate's certificate. The new path is quite as convenient as the old, and no objection is raised to the change. But disputes have been decided against the public largely on this point, for it is argued that, since everyone is expected to know that certain elaborate formalities must be complied with before the line of a public path may be lawfully changed, acquiescence in an irregular diversion may be taken to indicate that the path was not a reputed public way.

Far more dangerous, however, is the temporary or permanent obstruction of rights of way. Gates are occasionally locked, stiles bushed up, or hurdles placed across the route. The occasional obstruction of footpaths is sometimes tolerated from a mistaken neighbourly feeling. In a protracted action about a path near Purley, one of the main factors which led to the loss of the way was evidence that it had been the habit of the occupier of the land during the lambing season to place hurdles to form a sheep-fold in a corner of a field through which the way passed. People merely walked around the fold, but much was made by judge and counsel of the fact that they had tolerated this temporary obstruction without demur.

Definite forms of obstruction are more easy to meet, because they are more apparent. Sometimes formidable barriers are erected, and I recently inspected a path which had been obstructed by the cutting of a dyke 12ft. wide and 7ft. deep. In a case in which the Commons Society was concerned, and which occurred at Snettisham (*Norfolk County Council* v. *Green* (1904), 90 L.T. 451), waggon loads of railway sleepers were conveyed to the spot and deeply embedded across the path. Moreover, barbed wire entanglements were introduced which might have served as a model for the Hun. They were all removed by the sturdy village fishermen, whose action was upheld by the High Courts.

It is not always safe for members of the public to take the law into their own hands by removing obstructions. In any event, it is imperative that they should be certain that the obstructed path is a public way, and that they should do no more damage than is actually necessary to secure reasonable passage. Courts of Law view with suspicion the acts of a private individua who seeks to remedy a public nuisance by physica force. For instance, a few years ago a membe of the Commons Society removed a locked gate which had been erected across a carriage-road. Proceedings were taken against him, and he proved that the road was a public way. Nevertheless, he was ordered to pay the costs, because he had removed not only the gate but also the iron staples in the gate-posts into which the hinges of the gate had been fixed. It was held that he had done more damage than was necessary.

It will thus be realised that an owner seeking to deprive the public of a right of way has available a variety of methods of attack; and he can slowly build up a case, even when an ancient path is involved, to show, by a series of repressive acts, that he did not intend to dedicate a way and to raise the presumption that his predecessors did not do so either. He has also the enormous advantage of knowing that, whether he is plaintiff or defendant, the burden of proof lies on the side which is championing the public cause. It is necessary for the public to show upon what they base their claim of dedication before the owner is called upon for a reply. To the layman, therefore, the fight is bound sometimes to seem unfair, especially since the tenants and employees of an estate, for obvious reasons, cannot be called as witnesses to support a claim of right against the estate, and that, even if they were willing to testify, their special knowledge would be of little service because their user of the path would be deemed to have been privileged.

And the owner has also other great advantages. We have seen that all public rights of way which were not created under statutory authority must, in legal theory, have originated in dedication, and that the process of dedication is tantamount to the free gift or grant to the public of an irrevocable licence to use such ways. The only person who can make this gift or grant is the absolute owner of the freehold. A person who enjoys a limited interest in the property is not the actual freeholder and, consequently, it is held that he cannot burden the estate in which he is interested by the grant of a perpetual licence or easement in favour of the public.

A great proportion of the land in this country is in the hands of tenants for life; it is strictly

entailed or subject to family settlements, and it may have been in that condition for hundreds of years. The tenant for life is not the actual freeholder, and, therefore, he cannot, in a technical sense, dedicate rights of way in favour of the public, save in the manner permitted under the Settled Land Acts. If a break, however brief, in the family settlements can be established, the difficulty disappears; but judges differ in their method of dealing with disputes about rights of way on land which has been strictly entailed throughout living memory. Some insist upon proof that the public enjoyed the use of the alleged way before the family settlements commenced. For instance, the late Lord Alverstone, when Lord Chief Justice of England, tried a case with reference to a disputed roadway on the Trentham Estate of the Duke of Sutherland. Evidence was produced of actual public user for eighty-five years; there was little rebutting evidence and the issue seemed clear. The jury returned a verdict to the effect that a public right of way had been obtained by long user, but that the present Duke had not intended to dedicate—a fairly safe rider seeing that the road was obstructed whilst he was owner. This verdict was set aside by Lord Alverstone on the grounds that the land had been strictly and continuously entailed since 1760; that he had no evidence of the public use of the way before 1760; and that, since that time, no dedication could be presumed to have arisen by mere user.

If it were followed by all judges, this strict view of the law would render impossible the proof of public paths on estates which were entailed before living memory. Fortunately, however, other judges got over the technical difficulty by holding, in cases in which there is ample evidence of public user throughout living memory, and in which the user cannot be shown to have commenced during the period of settlement, that dedication must have taken place before the period of entail began. Lord Justice Chitty, in the course of proceedings with regard to a Sussex path, adopted this attitude, and brushed aside a claim that no public right of way could be proved because the estate had been entailed since the time of William and Mary, by saying that, if necessary, he would presume that dedication took place in the reign of William the Conqueror.

This uncertainty in the administration of the law is a serious hardship to litigants. The owner does not know what attitude a particular judge may adopt with regard to what may be his strongest line of defence. On the other hand, local authorities fear to embark upon litigation, even in cases where the evidence is overwhelmingly in favour of the public, because the existence of an unknown family settlement may be sprung upon them at the last moment.

Accordingly, a widespread feeling has arisen on both sides that the proof of public rights of way should be placed upon a more equitable and sure basis. In the case of private ways no ambiguity exists, for under the Prescription Act proof of unchallenged enjoyment for forty years is sufficient to establish a claim to a private easement even against a settled estate.

The Commons and Footpaths Preservation Society have, therefore, ever since 1907 been pressing for an alteration of the law, and on their behalf a Public Rights of Way Bill has made several appearances in Parliament. This Bill proposes that where an estate is in the hands of an actual freeholder, open and notorious public user of a path for twenty years shall be sufficient to raise the presumption of dedication. If, however, the estate is entailed, or subject to any other technical disability, it is proposed that the period of user shall be forty years. This Bill has met with little opposition, for the justice of its principles is recognised and the need for its passage is generally admitted. In different sessions it has passed the House of Commons and House of Lords by overwhelming majorities, but the time available for the discussion of private members' Bills is so brief that the Bill has not yet been approved by both Houses in the same session. It may be hoped that when normal times again come the Government of the day may be prevailed upon to give facilities for the passage of this useful measure.

Another serious difficulty in maintaining rights of way has arisen from the divergent views of judges on the question whether a public footpath may lead to a place of historic interest or natural beauty, or whether it must lead to another public way. Many of our most cherished paths are valued because they give access to a mountain top or glen, to a cliff, or to a ruined castle. A beautiful view is a national asset. It may have been available to the community for centuries and beaten tracks worn by the feet of many thousands of tourists may approach it. Nevertheless, some judges hold that such paths are permissive, and that they may be closed to the innocent enjoyment of the public unless a through route can be maintained. It is surely illogical to contend that, whereas a public high-

way in a town may be a *cul-de-sac*, every public right of way in the country must be a thoroughfare.

In the case of a path leading to a mountain top in Cumberland, a public right of way was established with the help of the Commons Society, which also assisted in the legal fight which led to the reopening of a road to the Giant's Causeway in Ireland. Unfortunately, however, in the case of public access to Stonehenge, the Society was defeated in its attempt to establish a public right of access.

The caging in of Stonehenge by means of a barbed wire fence and the charge of one shilling admission to the enclosure aroused violent opposition, for this famous circle of stones is recognised as the most imposing and interesting of all the prehistoric remains in England. For hundreds if not for thousands of years this early cathedral of the British race had been approached by deeply scored roadways which cross the Wiltshire Downs for long distances. It was alleged that the stones were suffering damage; but the Society pointed out that if that were the case it was open to the owner, while retaining all his proprietary interests in the monument, to constitute the Office of Works guardians of Stonehenge under the Ancient Monuments Act, and they would thereupon be bound to protect the remains.

It offered to raise £10,000 in order to purchase the owner's rights and to protect the stones without enclosure. This offer was declined, although, after first asking an enormous sum for his interests, the owner came down in price to £50,000. The Society felt that it would be neither right nor possible to raise this exorbitant amount, and with great regret Lord Eversley and the Committee eventually decided to institute legal proceedings against the owner, Sir Edmund Antrobus, who had obstructed the ancient tracks.

The hearing lasted seven days, and finally the judge decided against the Society's claims: in the first place, because the existence of a long-standing settlement was deemed to prevent the presumption of the dedication of through routes; and, in the second place, because, in his view, a public way could not end at a place of historic interest, such as Stonehenge.

This has been the only case in which the Society has suffered defeat in the Law Courts during a fifty years' fight for public rights of way, and the sympathy aroused by its efforts to maintain an important public principle has determined it not to rest content until this point, too, is finally settled by Parliament in accordance with the dictates of common-sense and equity.

In the meantime the death of Sir Edmund Antrobus led last year to the sale of Stonehenge. The monument realised at public auction £6,600—or £3,400 less than the Society offered to raise in 1901 in order that the remains might be permanently preserved for the nation. Stonehenge is still in private hands, and the estate is considerably poorer than would have been the case had the Society's offer been accepted.

Litigation with regard to rights of way is an expensive matter. The Stonehenge case cost the Society almost £4,000; that amount, although large, is small in comparison with costs which followed a bitterly-contested action about Yorkshire footpaths, and which amounted to over £15,000. Heavy expense is unavoidable, because a host of witnesses must be produced on each side, and also because the cost of investigating ancient titles is often considerable. By simplifying the law, and laying down fixed rules for the guidance of judges and counsel, the Society's Public Rights of Way Bill will greatly reduce the burden of expense in connection with footpath litigation.

It must not be thought that the Commons and Footpaths Preservation Society is a litigious body. That is not the case, and very few of the thousands of disputes which have been brought to its notice have found their way to a Court of Law. It frequently happens that a representation to the landowner involved is sufficient to secure a recognition of the public rights. It is a pleasing duty, too, to bear record that most highway authorities are determined to perform their duty to the community in the matter. There are naturally exceptions to this rule, but the relations between the Society and parish and district councils are, in general, of the most satisfactory and cordial character, and many councils make it a practice to refer to the Society for advice in every case arising in their areas with regard to rights of way.

Nor should it be imagined that all landowners adopt the attitude of the autocrat who proudly said—

> "I am monarch of all I survey,
> My right there is none to dispute."

There are, it is true, too many owners who are willing to sacrifice public rights upon the altars of their private convenience, but the majority have come to recognise that the Society invariably endeavours to act with impartial justice to

both sides, and that it will not bolster up a weak or improper case. One happy result of this growing appreciation of the Society's principles and practice, has been that, during the last few years, it has often been asked to arbitrate between landowners and local authorities in cases of disputed rights of way. In its *rôle* of arbitrator the Society has been able to settle hundreds of vexatious footpath disputes to the satisfaction of the public and of the landowners, and at the present time disputes with regard to no fewer than 147 ways are awaiting adjustment at its hands.

By means of friendly settlements of this kind, legal proceedings, with all their attendant friction, expense and dissatisfaction, are obviated. Above all, the bitter memories which follow an unsuccessful footpath fight are avoided, for no feeling is created that might prevails over right.

Nevertheless, it is only by incessant watchfulness that our field-paths and woodland tracks are maintained. Gradually, through the efforts of the Society and its branches, footpath maps will cover a great part of the country. But this work is laborious and expensive, and, of necessity, it must proceed slowly and with care. In the meantime the cult for country rambling is growing in response to the facilities offered by rail, omnibus, and tram for rapid and cheap passage to the green fields. This development leads to fresh dangers, for experience has shown that a few irresponsible town-dwellers may render not only themselves, but the rambling community at large, unpopular with farmers when they wantonly trespass or ignorantly damage hay or other growing crops. Privileges, appreciated by many, may be withdrawn in consequence of thoughtless abuse by a few irresponsible individuals.

It may be, as Mr. Richard Whiteing suggests in his book "All Moonshine," that the time is coming when the development of aeroplanes may render unnecessary terrestrial tramps, but, as he takes care to add, the Commons Preservation Society will even then find it essential to open a Vault of Heaven branch.

In the meantime, it is estimated that there are in this country not fewer than 300,000 public paths. Each one of that great multitude is an asset of rural life, the preservation of which is worthy of some sacrifice. From the hour when the tender green of springtime first appears, to the closing months of the year when "autumn's golden arm enfolds the world," the charm of the footpath way acts as a magnet to the man whose heart is open to the touch of nature. The Commons and Footpaths Preservation Society, as the unofficial guardian of public rights and privileges, may also claim some share of his thoughts and sympathies in its ceaseless efforts to hand on to future generations those highways and byways which are now so great a boon.

DISCUSSION.

The Chairman (the Right Hon. Lord Farrer), in opening the discussion, said that, while our nation and its Allies were engaged in fighting for the freedom of the seas, the author was constantly fighting for the freedom of the land. One point mentioned in the paper had always puzzled him, namely, why was it that the Roman roads that existed all through Great Britain disappeared on the departure of the Romans? With regard to the author's suggestion that lawyers enrolling for National Service should be employed in codifying the various Acts dealing with highways, he was not sure that codification was always of advantage; and at any rate he thought it would be difficult to improve in that respect on the Act of 1836, which was a codification of the common laws and common customs of many centuries.

Mr. James Ellis referred to the fact that many of the old Roman roads were still in existence and being used at the present time. Men were gifted with faculties to appreciate the beauties of nature, and whether the author led them through field or forest, or highway or byway, he could show them where those beauties were to be found and could act as an ideal guide, philosopher and friend.

Mr. John Slater, F.R.I.B.A., said he had listened to the paper with very great interest. It seemed to him that if legally dedication was the first thing which gave a right to a footpath, surely user must have preceded it. The footpaths that were found all over the country must have been made by people who wanted to get somewhere, so that they must have had the user of them long before there was any dedication at all. With regard to the Chairman's remarks about the strange disappearance of the Roman roads, a similar case was that of the stately mansions erected in the time of Queen Elizabeth, many of which had completely disappeared. On the Continent also the Roman roads had vanished; he knew of a place in France where there was a beautiful archway which was evidently the entrance to a Roman way that had completely disappeared.

Mr. W. Whitaker, F.R.S., mentioned that the law with regard to cycling along public paths was rather singular, as cycles were looked upon as carriages,

with the result that a man might ride a horse along a path, but not a cycle. He would be glad if the author could say what was the essential width of a bridle path; it was mentioned in the paper that the public had a right from hedge to hedge, but if the hedges gradually grew nearer and nearer together the right was not worth very much. At Croydon there was an energetic branch of the Commons and Footpaths Preservation Society, whose members recorded on a map all the stiles and signposts and gates that they encountered on their walks, and he thought that plan might be followed in other parts of the country in order to avoid the setting up of obstructions. It was the duty of the public to help in the preservation of their rights; if they did not, those rights would be lost to them. The author had given several instances of cases where rights of way had been lost simply for want of being looked after, and he hoped people would take warning from that, and give their support to the Commons and Footpaths Preservation Society. He thought it was not sufficient merely to put up a sign indicating that a certain footpath was public, but there should also be a notice indicating the place to which the path led.

Mr. Randolph A. Glen said that, with reference to the question of dedication, he did not think the author had made it clear that in dedication there were two things. There must be an intention on the part of the owner to dedicate, and there must also be user by the public, which meant acceptance by the public. The theory was that the owner said to himself, "I will allow the public to cross my land between two points," and that the public then went between those two points and made a track on the ground. What happened in practice, however, was that the public wanted to travel between two points; they saw a convenient place to cross at, and in crossing they made a track on the ground. Subsequently the owner saw the track, and if he did not take steps to prevent the use of it, he was presumed to have intended from the commencement of the public user that the public might go that way. The Courts did not pay any attention to the actual moment of the commencing of the user or the actual moment of the intention to dedicate. With regard to the codification of the law relating to highways that the author advocated, he did not think that was necessary, as the law was quite plain at the present time. He thought what was required was an amendment of the law, as set forth in the Rights of Way Bill. Codification was not so much required as the abolition of the ridiculous rule with regard to strict settlement. The real hardship from which the public were suffering was that they lost their right simply because for many years the landowner had been a person who was unable to dedicate because of that strict settlement. In Scotland at the present moment only forty years' user had to be proved in order to establish a right of way, and the Commons and Footpaths Preservation Society wanted that law to be applied to England as well. If the owner of the land at the time was also the freeholder and able to dedicate, the period should not be forty years, but twenty years.

On the motion of the Chairman, a vote of thanks was accorded to the author for his interesting paper.

Mr. Chubb, in reply, after thanking those present for the cordial reception they had given to his paper, confessed that he could not offer a satisfactory answer to the Chairman's question with regard to the disappearance of Roman roads, as he had never been able to understand why those roads had disappeared. The failure of the system of ordered government which followed the withdrawal of the Romans, and the cessation of the use of roads by chariots, might have tended to obliterate the surfaces of the roads, and their destruction was accelerated, at all events in some places, by the removal of the valuable materials which formed the deep highways for the purpose of making fences and walls, and even buildings. It was remarkable that they had disappeared, but he thought it still more remarkable that many of them had disappeared quite recently. There was, unfortunately, no statutory width laid down for a bridle path, a footpath, or a carriage road that did not lead to a market town; it depended on the width that the public had actually used in the past. There were certain stipulations with regard to the width of paths leading to market towns, in order that the surveyor of highways might have authority to clear away obstructions at the side of those paths. The reason why a cyclist was not entitled, strictly speaking, to ride along a bridle path was that a bridle path was a highway limited to the use of foot passengers and horsemen. There was seldom any objection raised to a cyclist using a bridle path, but in a technical sense a cycle was deemed to be a vehicle. He hoped all those interested in the subject of his paper would constitute themselves unofficial guardians of the public right of way.

RED PEPPER TRADE OF SOUTH INDIA.

According to a report by the United States Consul at Madras, the Presidency of Madras is by far the largest producer of chillies (red pepper) in India proper, followed ordinarily by Bengal and the Punjab. The area devoted to this culture cannot be stated definitely, as the plants are most frequently raised as borders to fields or as lines through fields. In Eastern and Northern Bengal, however, capsicum becomes a regular field crop. In the Madras Presidency chillies are raised for commercial purposes principally at Guntur, Nellore, Erode, Salem, and

Ongole, where the plant thrives best in irrigated lands. The commonest form is the *Capsicum annuum*, to which the Bombay, Japan, and other long capsicums belong. The surplus crop of chillies, or that not used for domestic consumption in the fresh state, is dried and exported.

The name "Bombay capsicum" has become applied to nearly all red pepper exported from the west coast, even though the product may have originated in the Madras Presidency. This variety is 2 in. or 3 in. long, with a thick skin and a heavy stem. It is usually the cheapest grade available for grinding and, when bright-red, clean pods are secured, will produce a good coloured powder of considerable strength. The Bombay capsicum is mixed with mombessa and other strong chillies by many grinders to produce a strong ground red pepper at a moderate price.

The shipments to all countries in the fiscal year ended March 31st, 1915–16, amounted to 8,050,911 lb., valued at £102,100. The yearly crop in South India is estimated at about 4,000 tons. In India red pepper is much used as an ingredient in all curries and many other food preparations by every class of the community. In Bengal an extract of the consistency of treacle is regularly prepared and sold. The green fruits are pickled or cooked fresh with special dishes, and even eaten raw.

LAKE COLERIDGE WATER-POWER SCHEME: FIRST YEAR'S OPERATION.

The results attained by the Government scheme for the development of hydro-electric power from Lake Coleridge, which has been in continuous operation for a complete year, have, according to the Public Works Statement for 1916 of the New Zealand Minister of Public Works, justified the most sanguine anticipations. The lake, which is some ten miles long, is situated in the Canterbury Province, in the basin of the Rakaia River. Three units of generating machinery were originally installed, capable of an output of 6,000 h.p. Twelve months ago the demand for current warranted the installation of a fourth unit of 2,000 h.p., and the expanding business now necessitates the addition of a fifth unit, comprising pipe-line, turbine and generator of 4,000 h.p. During the year the maximum load on the plant reached 1,770 h.p., which is less than the capacity of any one of the units installed. Under these circumstances the business could not be expected to show a profit, but, on the other hand, at the end of the year the plant was earning sufficient to cover working expenses. Contracts to the extent of 8,000 h.p. have already been entered into, and when the power under these contracts is being supplied it is confidently expected that the plant will be earning sufficient to pay interest in full as well as working expenses.

The power has, up to the present, been utilised mainly for public (lighting, etc.), domestic and certain industrial purposes; further arrangements are now in hand for utilising the current for tramway traction and for the operation of machinery in the principal meat works, flour-mills, tanneries, dairy factories, and the established industries in and around Christchurch. During the year feeder lines have been extended to Belfast, and arrangements are being made for a further extension in that direction to Kaiapoi.

In addition to supplying power for present known requirements the Department of Public Works is in touch with manufacturers in many branches of industry with a view to introducing new processes or improving existing ones where such possibilities are opened up by the large supply of electric power available. It is probable that one result will be the establishment of new electro-chemical industries, and possibly the manufacture of steel.

ARTS AND CRAFTS.

Arts and Industry.—Some time ago the council of the Imperial Arts League drew up a memorial which was sent to the Commercial and Industrial Committee presided over by Lord Balfour of Burleigh. In response to the Committee's request the League has now sent a further memorandum setting forth the necessary connection between art teaching and manufacturing interests, and offering certain practical suggestions with regard to the organisation of the teaching of industrial art in this country. The document will, doubtless, be regarded very differently by people of various schools of thought, and possibly even those who are in sympathy with its views and aspirations as a whole may doubt whether the foundation of an independent "Industrial Art Department," "working in conjunction with the Board of Trade and the Board of Education," would necessarily be a very effective measure of reform or would be the best possible means of furthering industrial development along sound artistic lines. However that may be, the council of the Imperial Arts League must be counted as having done real service to the nation at this juncture in bringing forward a scheme in which they insist, sanely and firmly on the importance to trade and manufacture of high ideals in taste and the necessity for linking up the art schools in industrial centres with the industry of the locality and the close connection between technical and art training. The recommendation that South Kensington should augment the extent and distribution of its travelling collection will be welcomed by many teachers, and the reminder that the Victoria and Albert Museum was founded for designers and manufacturers is one which, in view of

much common talk, needs repeating and emphasising. The suggestion that "permanent and properly-housed Industrial Exhibitions of examples of modern industry" should be established is not, of course, new, and most of us remember attempts somewhat in this direction which have not been entirely successful; but there seems no reason why difficulties of this kind should be allowed to stand in the way of what might be a really useful institution. There is urgent need at the present moment for impressing both upon artists and manufacturers in the interests of our national trade and industry now, and still more after the war, the intimate relation between art and manufacture and the services which they can render to one another. If the importance of this matter has been brought home to the Commercial and Industrial Committee a very great deal has been gained.

Graphic Arts and War Memorials at Burlington House.—The Winter Exhibition of Graphic Art at the Royal Academy is worthy of more attention from the point of view of Arts and Crafts than might be expected from a collection with such a title housed at Burlington House. Besides the very interesting retrospective section, it contains drawings, wood engravings, etchings, dry points, aquatints, mezzotints, lithographs and colour prints by the principal graphic artists of the day, and it shows incidentally the kind of work which is available for various trade purposes. Not only can the publisher discover from the exhibits where to obtain illustrations and book decorations of various kinds, and what is being done by artists of widely different schools and concerned with a variety of techniques, but the business man, with an eye to the production of a really good and artistic catalogue, showcard or what not, will find much that is of use to him. There are examples, too, of designs for certificates and the like which are of interest from a decorative standpoint. Apart from purely practical considerations, it would be difficult to overestimate the value of the exhibition as throwing light on recent developments in the graphic arts, showing how much has been achieved recently both technically and artistically, and helping the general public to realise the influence of such comparatively modern artists as Whistler, Beardsley and Phil May, as well as masters of a rather earlier date, upon present-day work.

One section of the exhibition is devoted to designs for war memorials. These are largely sketch models on a very small scale for large and imposing monuments to be erected by corporations and public bodies, and it is rather difficult to judge from them just how far the finished work would or would not be successful, though some of them show considerable promise. Amongst the rather less ambitious exhibits, Mr. W. Reynolds-Stephens's little kneeling angel, suggested as a memorial to one of our fallen heroes, may be noted as peculiarly charming and attractive. Mr. Alfred Drury's war medal is a dignified piece of work, and some of Mr. Nelson Dawson's small memorials are, in their characteristically massive way, of real artistic interest. One or two of the designs for wall tablets to be erected in memory of eminent men suggest the reflection that such work is not always best carried out by artists distinguished in some other branch of art, even if they happen to have some care for decorative effect.

The Mace for the Dominion House of Commons.—It is both fitting and graceful that the new mace for the House of Commons of the Dominion of Canada should be presented to that assembly by the Lord Mayor of London (Sir C. C. Wakefield) and the Sheriffs who were in office when the Parliament House at Ottawa was burnt down. There is also a good sentimental reason for keeping the design of the new mace on similar lines to those of that used in the House of Commons of the Mother Country, with such differences as are entailed by the necessity for including the arms of Canada and the desirability of introducing such emblems as the maple leaf and the beaver. This close adherence to the old form has resulted in the production of a very handsome and dignified piece of plate worthy in many respects of both the donors and the recipients, and creditable to the Goldsmiths and Silversmiths Company whose work it is. From the point of view of the encouragement of British art and the expression of more modern feeling one cannot help thinking that an opportunity has been lost. There is nothing about the mace which suggests a vigorous modern art movement in this country. A choice had to be made between two opposing sets of ideas, and it is quite possible that it was wisely made and that the Dominion House will be better content that their mace should be very much like the British one than that it should represent the artistic ideals of the present day. Whether British artists will agree with them is quite another matter.

OBITUARY.

The Duke of Norfolk, K.G., G.C.V.O.—The Duke of Norfolk died at his residence in St. James's Square on the 11th inst. at the age of sixty-nine.

Born in 1847, he succeeded his father, the fourteenth duke, in 1860, and in the same year he began his school life at Cardinal Newman's school at the Oratory. At the age of seventeen (as Roman Catholics were at that time debarred from attending the universities) he was sent to travel, and he stayed for a considerable time

with his uncle, Lord Lyons, then Ambassador at Constantinople.

While still a young man he began the work for his co-religionists which was to last to the end of his life. He came to be known abroad as the lay representative of the Roman Catholic Church in England, and as such he was selected as the natural leader of the special mission to the Pope which took place in 1887.

The Duke's public services, national and municipal, were many and various. In 1895 he was appointed Postmaster-General under Lord Salisbury's Government—an office which he resigned in 1900 in order to volunteer for active service in the Boer War. He frequently sat on Royal Commissions, and took a continuous and deep interest in his work in the House of Lords, although he did not again accept office.

He served as Mayor of Sheffield, where he owned a great deal of property, from 1895–1897. In the latter year the Mayoralty of the city was raised to a Lord Mayoralty, and the Duke thus became the first Lord Mayor of Sheffield. His benefactions to the local parks and recreation grounds were on the grand scale, and he also took a leading part in the establishment of the University of Sheffield, of which he was the first Chancellor.

As hereditary Earl Marshal, the Duke held a post for which he was peculiarly suited, for he was keenly interested in public ceremonial, and he was responsible for the arrangements at the coronations of King Edward VII., and of his present Majesty.

The Duke became a Fellow of the Royal Society of Arts in 1914, on the nomination of Lord Sanderson, who had just retired from the Chairmanship of the Council. He was at once elected a Vice-President of the Society, and he continued to hold this office until his death.

FREDERICK WILLIAM HARRIS.—The death occurred at Bournemouth, on the 2nd inst., of Mr. Frederick William Harris, Chairman of Messrs. Harris & Dixon, Ltd., in his eighty-fourth year.

At the age of twenty-one, Mr. Harris was admitted a partner in the firm of Bentley, Harris & Dixon. He was one of the founders of the Commercial Union Assurance Company, and remained a director of this company and a member of Lloyd's until his death. At one time he was deeply interested in the development of the South Wales coalfield, and he sank Harris's Deep Navigation Pits, which are now amalgamated with the Ocean Collieries. He was a Lieutenant of the City of London, a member of the Council of the University College of South Wales, a Past-Master of the Drapers' Company, and for many years Chairman of the Coal Factors Society.

He was elected a member of the Royal Society of Arts in 1897.

GENERAL NOTES.

DECLINE OF SHEEP-FARMING IN SWITZERLAND.—According to a statement recently made by a member of the Swiss Federal Council, it appears that the total number of sheep in that country has decreased, during the last fifty years, from 4,500,000 to 1,710,000 head. It was considered that steps should be taken by the Federal Government to encourage sheep-farming and take immediate steps to provide against a scarcity of meat in that country.

POTASSIUM CHLORIDE IN JAPAN.—The output of potassium chloride in Japan is now sufficient to meet the home demand. The annual consumption of potassium chloride in Japan is about 4,000 tons (according to the *London and China Telegraph*), the greater part of which was supplied, prior to the war, by Germany and other European countries. Since the war broke out prices have increased five-fold. Stimulated by high prices, many new potassium-making companies have been established in Japan. Whereas before the war there was only one Japanese chemical company, which was producing three hundred tons a year, there are now a number of companies largely engaged in the manufacture of this product in the Hokkaido, Awa, Kadzusa, Shimosa, and other districts, and official statistics show that at present the output is over 3,500 tons. Since August last considerable export business has been done to Vladivostock, China, and Sourabaya. Thus, 302,512 lb. were exported in August and 231,756 lb. in September.

A MERSEY TRAFFIC TUNNEL.—The project of constructing another tunnel under the Mersey between Liverpool and Birkenhead has been revived. There are two schools of opinion on the subject, says the *Times*, one favouring a traffic tunnel and the other advocating a great bridge. Sir William Forwood, in urging that a traffic tunnel is necessary, estimates that it would cost £1,200,000, with tracks for both slow-moving and fast traffic, but would be less expensive than a bridge as a means of relieving the enormously-developed cross-river goods traffic. It is pointed out that the congestion and delay in this traffic under present conditions is bearing hardly on the trade of the port, and that something will have to be done to provide permanent relief, especially in view of the future growth of Liverpool's trade. Sir William Forwood suggests that a tunnel might be approached by a subway with a gradient of, say, 1 in 20, a spiral roadway descending at that gradient 120 ft. or 150 ft. to the mouth of the tunnel. Such a spiral would not occupy more than an acre of land, and there is ample room for its construction at the pier head. The centre of the spiral might be used for passenger lifts, but passenger traffic could also be conveyed in motor or electric trains.

Experiments in the Rearing of Blue Foxes.—An arrangement has been made between the Bureau of Fisheries of the United States Department of Commerce and the Bureau of Biological Survey, Department of Agriculture, for experimental work in the rearing of blue foxes. The Fisheries Bureau will supply the Biological Survey Bureau this season with six pairs of blue foxes from the Pribilof Islands, Alaska, for use on a fox farm in the State of New York. The price commanded for blue-fox pelts naturally makes the question of the possibilities in the way of breeding the blue fox in captivity of considerable interest. The problem has been undertaken by various persons in different regions, but the Bureau of Fisheries is not aware that definite results have been obtained. It is hoped that the work of the Biological Survey in this respect will develop methods for successfully rearing this animal in captivity from the standpoint of a profitable fur-producing business.

Bauxite Deposits in Dutch Guiana.—From a report by the United States Consular Agent at Paramaribo, it appears that bauxite was discovered in 1915 by a mining engineer on private properties situated on the Surinam River, four hours' journey from Paramaribo. The area over which the bauxite deposits have been found, and which discloses various outcrops, is sixty-two miles long and six and a quarter miles wide. It is not yet possible to give any idea of the amount of bauxite within this area. Very little prospecting has been done. In wet, tropical countries like the Guianas there is extensive decomposition. The damp heat, aided by decomposed vegetation, tends to make surface indications difficult for the prospector. On the northern fringe of the deposit there is a large percentage of iron, assays showing as high as 33 per cent., whereas the southern fringe shows less than 2 per cent. Silica contents are low at both points. It is probable that the greater part of the given area is made up of bauxite, and that the mineral will be discovered at various depths, the formation being of a wavy nature. Several broad and deep rivers run through the course of the formation, making it easily accessible for transportation.

MEETINGS OF THE SOCIETY

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

February 21.—Mrs. C. Hoster, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment." Lady Emmott will preside.

February 28.—Francis A. Hocking, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs." Robert Hutchison, M.D., F.R.C.P., will preside.

March 7.—James Harris Vickery, LL.B., "German Business Methods."

March 14.—Dr. J. Augustus Voelcker, "Fertilisers and their Supply in War Time."

March 21.—G. W. Jones, "Colour Printing and some Recent Developments." Carmichael Thomas, Chairman of the *Graphic* and *Daily Graphic*, will preside.

April 18. — Horace M. Thornton, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

April 25.—Sir Francis Fox, M.Inst.C.E., "Flour and Bread." Captain Charles Bathurst, M.P., Parliamentary Secretary, Ministry of Food, will preside.

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

March 15.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

April 19.—D. T. Chadwick, I.C.S., "The Future of Indian Trade with Russia and France."

May 17.—Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

February 27. — Alfred Bigland, M.P., "Imperial Assets and how to use them."

March 27.—The Hon. Frederick W. Young, LL.B., Agent-General for South Australia, "Land Settlement in South Australia."

May 1.—Philippe Millet, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

Sir C. Arthur Pearson, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

Joseph Pennell, "The Artistic Aspects of War Work."

Gabriel Gordon Cleather, "The Drum."

Dr. M. Horn, "The Belgian Colonies."

Professor William Ripper, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency."

Cantor Lecture.

Monday afternoon, at 4.30 p.m.:—

PROFESSOR A. BERESFORD PITE, F.R.I.B.A., Royal College of Art, South Kensington, "Town Planning and Civic Architecture." Four Lectures.

Syllabus.

LECTURE IV.—FEBRUARY 19.—*The Housing and Town Planning Act*, 1909. Problems for solution. Procedure. Advice to promoters. Preparation of schemes. Architectural considerations. Examples of Garden City movements—Letchworth, Hampstead, etc. The problem of London.

Howard Lectures.

Monday afternoons, at 4 p.m.:—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies: (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market." Two Lectures.

April 30, May 7.

Aldred Lectures.

Monday afternoons, at 4.30 p.m.:—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

March 5, 12, 19.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor A. Beresford Pite, "Town Planning and Civic Architecture." (Lecture IV.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Dr. T. G. Pinches, "From World Dominion to Subjection: the Story of the Fall of Babylon."

Bibliographical Society, 10, Hanover-square, W., 5 p.m. Mr. G. F. Barwick, "The Laws regulating the Book-Trade in Italy."

Chemical Industry, Society of (London Section), at Lyon's Birkbeck Café, High Holborn, W.C., 7.15 p.m.

Geographical Society, Burlington-gardens, W., 5.30 p.m. Mr. H. C. Woods, "The Baghdad Railway and its Tributaries."

TUESDAY, FEBRUARY 20...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor J. S. S. Brame, "Liquid Fuel and its Combustion."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Dr. J. Brownlee, "The Relation of Infantile Mortality to Mortality in Subsequent Life."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Pain and its Nervous Basis." (Lecture VI.)

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. F. J. Norman, "Period Furniture and Upholstery."

Photographic Society, 35, Russell-square, W.C., 7 p.m. 1. Mr. B. Cox, "Some Observations on Clouds." 2. Mr. T. H. B. Scott, "Some Observations on Photographers."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. C. J. C. Pool, (*a*) "Notes from the Caird Insect House, with exhibition of specimens and lantern-slides"; (*b*) "The Coleoptera of the Family *Cissidæ* found in Britain, with Descriptions of two new Species. A new Species of the Coleopteran genus *Cryptorrhynchus* Illiger." 2. Mr. A. de C. Sowerby, "On Heude's Collection of Pigs, Sika, Serows, and Gorals in the Sikawei Museum, Shanghai." 3. Mr. G. A. Boulenger, "On the Lizards of the genus *Philochortus* Matschie."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Discussion on Mr. G. W. Humphreys' paper, "The Main Drainage System of London." 2. Mr. J. L. Hodgson, "The Commercial Metering of Air, Gas, and Steam."

WEDNESDAY, FEBRUARY 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mrs. C. Hoster, "The Training of Educated Women for Secretarial and Commercial Work, and their Permanent Employment."

Aëronautical Society of Great Britain, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Captain G. S. Walpole, "The Less Satisfactory Materials of Aircraft Construction."

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Mr. W. H. Dines, "The Heat Balance of the Atmosphere." 2. Mr. C. E. P. Brooks, "Continentality and Temperature."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. T. D. Lister, "The Tuberculosis Problem in War Time."

Oriental Studies, School of, London Institution, Finsbury-circus, E.C., 5 p.m. Miss A. Werner, "The Bantu Languages."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Mr. A. Yusuf Ali, "Modern Hindustani Drama."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7 p.m. Discussion on "Fuel Economy."

(Yorkshire Section.) Philosophical Hall, Leeds, 7 p.m. Mr. J. Shepherd, "Some Points in Connection with Engineering Specifications."

THURSDAY, FEBRUARY 22...Geographical Society, Kensington Gore, W., 5 p.m. Mr. J. T. Jutson, "The Origin and Growth of the Dry Lakes in Western Australia."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. S. Prior, "Memorial Art in History." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. M. Emile Cammaerts, "Belgium as a Nation."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. R. N. Sinclair, "Southampton Docks, Remodelling of an Old Dry Dock."

FRIDAY, FEBRUARY 23...Royal Institution, Albemarle-street, W., 5.30 p.m. Mr. H. Wickham Steed, "Some Guarantees of Liberty."

Economics and Political Science, London School of, Clare Market, W.C., 5 p.m. Mr E. F. Hitchcock, "The Importance of Imperial Wool."

University of London, University College, W.C. (Slade School), 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture VI.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, FEBRUARY 24...Royal Institution, Albemarle street, W., 3 p.m. Mr. D. Jones, "The Pronunciation of Languages in General." (Lecture I.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—February 16, 1917.

Journal of the Royal Society of Arts.

No. 3,353. VOL. LXV.

FRIDAY, FEBRUARY 23, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, FEBRUARY 27th, at 4.30 p.m. (Colonial Section.) ALFRED BIGLAND, M.P., "The Empire's Assets and how to use them." W. A. S. HEWINS, M.P., will preside.

WEDNESDAY, FEBRUARY 28th, at 4.30 p.m. (Ordinary Meeting.) FRANCIS A. HOCKING, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs." ROBERT HUTCHISON, M.D., F.R.C.P., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

At the last meeting of the Council, on Monday, the 19th inst., COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., was elected a member of the Council and Vice-President of the Society, in place of the late Duke of Norfolk, K.G., G.C.V.O.

CANTOR LECTURE.

On Monday afternoon, February 19th, PROFESSOR A. BERESFORD PITE, F.R.I.B.A., delivered the fourth and final lecture of his course on "Town Planning and Civic Architecture."

On the motion of the CHAIRMAN a vote of thanks was accorded to Professor Beresford Pite for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

HOWARD LECTURES.

The Howard Lectures on "Coal and its Economic Utilisation," by JOHN S. S. BRAME, Professor of Chemistry, Royal Naval College, Greenwich, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures, which have been published separately and are still on sale, can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 21st, 1917; LADY EMMOTT in the chair.

The following candidate was proposed for election as a Fellow of the Society:—

Willis, Henry S., Weardale House, Wearhead, Co. Durham;

and as an Honorary Corresponding Fellow:—

Belaiew, Colonel Nicholas T., C.B., Chemical Laboratory, Michael Artillery Academy, Petrograd, Russia.

The following candidates were balloted for and duly elected Fellows of the Society:—

Beaumont, Ivor, A.R.C.A., F.I.B.D., 74, Addison-way, Hampstead Garden Suburb, N.W.

Bebianno, Affonso, 858, Rua Barão de Mesquita, Rio de Janeiro, Brazil, South America.

Gaunt, Edgar Lawson, "Nethway," Horsforth, near Leeds.

Jones, George W., Gough-square, E.C.

Mervyn-Howell, William, 13, Cathedral-road, Cardiff; and 3, Essex-court, Temple, E.C.

Starr, David Alfred, Clyde Valley Electrical Power Company, 53, Bothwell-street, Glasgow.

THE CHAIRMAN, in introducing the reader of the paper, said there was no one who had a greater knowledge of the conditions of clerical work, of what was necessary in the way of training, of how that training should be undertaken, and the right posts that women and girls should occupy after they had been trained, than Mrs. Hoster. Since

the outbreak of the war great changes had naturally come about, and the present condition of things was a somewhat unsettled one. The spirit of the response made by the women of the country had been splendid; but at the same time many women regretfully felt it had shown there was a large amount of latent ability that was untrained. At the present moment there was a vast number of girls who had taken employments of different kinds for which they had no sort of training, and she thought the Government was the biggest sinner in this respect; they had entirely gone in for quantity without any idea of quality. Many women felt that the wages offered for some of the work were far too high, while for the more skilled work they were far too low. She looked upon the thorough training given by the author as a remedial measure for any future work undertaken in an amateurish spirit. It was extraordinarily difficult to know what would happen when the reconstruction came after the war. All the women who had been doing a certain amount of work during the war would not care to remain at home in the future; they had, for the first time, got a taste for work, but they would be launched out, not as substitutes for men, but in competition with men. That was the great difficulty and the great danger. She knew it was not a very popular subject at the moment to say that women should not be undertaking work when they were not trained for it, for the simple reason that women were so keen to do something. It was because she was so anxious that the views which Mrs. Hoster held should become known to big employers of labour, and above all that her views should be instilled into some of the Government officials who had the ordering of things, that she had such great pleasure in accepting the invitation to preside over the meeting.

The paper read was—

THE TRAINING OF EDUCATED WOMEN FOR SECRETARIAL AND COMMERCIAL WORK, AND THEIR PERMANENT EMPLOYMENT.

By Mrs. Constance Hoster,

Hon. Secretary of the Society for Promoting the Employment of Women.

I have been asked to speak to you on the training of educated women for secretarial and commercial work and their permanent employment, and I would like to preface my words by saying that I fully realise that at the moment *training* is not a popular subject; but the one way for women—especially educated women, with whom I am more particularly dealing—to find a permanent place in the world of work is by *training*.

The Society for Promoting the Employment of Women, of which I am honorary secretary, has worked for fifty-seven years to prevent the overburdening of the labour market with unemployable — because untrained, or only partially trained—women.

When this Society started it had to instruct the public in the fact, not only that many women were already self-supporting, but that the majority of those who were so were supporting themselves under very adverse conditions for lack of a suitable training.

The old opinion that women are necessarily provided for by their men relations, though still often quoted, cannot, I think, be honestly believed by many people in these days; but it is astonishing to find how few have grasped the idea that since woman has to compete for her livelihood in the open market it is grossly unfair to allow her to do so without the equipment that public opinion takes it for granted will be supplied to her brother.

I quite realise that these are, of necessity, days when most of us find it easier to live in the present, and not to look to the future for fear of what it may hold for us. And surely this is not to be wondered at, for to go on from day to day, looking neither before nor after, is the only way in which many are able to live at all.

But this is not sufficient: more is asked of us, and more is expected. We *must* look to the future, not for our own sakes, but for the sake of others—of those who are to come after us, and, above all, for the sake of our country, her interests and her welfare. While her men are fighting in her defence, surely it is not too much to ask of her women that they should give thought to the future. As Herbert Spencer says: "To fit us for complete living is the function which education has to discharge."

I have this subject very much at heart, and I must again and again urge the necessity for *thorough and complete training* for our young people, so that they may not only be in a position to undertake successfully the branch of work for which they are best fitted, but also that they may be able to raise and maintain the standard of pay for competent work.

One of the results of the war will be that many will have to earn who hitherto have not been obliged to do so, and it is to those especially that I appeal to-day.

The only really successful worker is the worker who has been trained and who has made herself efficient in her own special branch. Anyone who considers the question at all must realise that after the war the labour market will be flooded with half-trained workers who

will be a danger to themselves and to those who are highly efficient and trained. Therefore it is easily understood that the greater the number of these highly-efficient and trained workers, the greater their power to uphold the highest standards of work and pay, which otherwise the half-trained, by sheer force of numbers, would tend to lower.

The country at all times requires our very best, and though it has been compelled in this crisis to accept in many cases the services of the untrained, people are beginning to see that this is not as it should be, and that there is no reason why it should continue. Only a day or two ago I read these words:—

"There is not the smallest doubt that in all Government Departments money is being wasted on salaries paid to incompetent girl typists. It is not the girls' fault in many cases. Demands were made for large numbers to come forward, and it was stated that previous experience was unnecessary. As a result hundreds of girl milliners, dressmakers, shop assistants, and the like, offered their services and were accepted. They have done their best certainly, but without the necessary training and education it is impossible for them to attain the level of the woman with years of study and experience behind her.

"A woman holding a responsible position in one Ministry gave her opinion that the work of her special department could be just as well carried out by half the number of secretaries employed at present, provided trained workers could be substituted for the untrained or partially-trained girls now employed."

Our young people should be persuaded therefore to consider that the best course to follow is to equip themselves *now* for the needs of the future and to avoid short emergency trainings as against national interest. Yet how difficult it is to think of training now when everyone is being implored to give her services trained or untrained. But training *is* just what is needed to make women's work permanent after the war.

To look at the matter from another point of view, the services of the trained will not be dispensed with even after our soldiers and sailors return. There is bound, unfortunately, to be a shortage of men, and the efficient women will be kept to work side by side with the men whose places they have helped to fill in a time of stress.

It must also be remembered that many of those who, feeling that they would like to do "something to help," offered themselves for clerkships, etc., will not, even if they could afford to do so after the war is over, be content to remain at home again more or less idle.

Yet it requires little imagination to realise that hundreds of these will be the first to be thrown out. Therefore they cannot be too strongly urged to have definite training now for whatever profession they wish to enter, instead of waiting till the war is over. Quoting from a writer to the *Evening News* of January 8th:—

"The trouble is that the girls who in the ordinary course would have been training last year have gone into the War Office and other offices without training. Of course, they will never get more than 25*s.* a week, and, after the war, they will all be out of work.

"Some of the training schools are even sending typists out half trained. Girls came from one of them to do some work for me, and they did not know what carbon paper was! And the wage they were asking was 25*s.* to 30*s.*"

Then, again, take the position of the quite untrained at present receiving small salaries which do not constitute a living wage, but which, after all, are a fair equivalent for the work done. They have little idea of the routine of an office—or, indeed, of office methods and organisation—and, however good their intentions, they must come short of much that makes a really good worker.

I do not wish to imply that we do not owe a great debt of gratitude to those who have so whole-heartedly thrown themselves into the breach and have helped at a time when their help was most needed, but I do desire to point out the danger in the future if "thorough training" is not now taken as our motto.

Perhaps you will allow me to tell you why your Secretary has suggested that I should be the one to give an address on this subject. For over twenty-four years I have been in the midst of women's work, and have come into contact with it from an absolutely practical point of view. In addition to training for all secretarial positions at my offices, I have a registry which was first started for my pupils, but as I have always wished to take only a limited number of these I found that I had many more posts at my disposal than applicants to fill them, and therefore instituted the free registry for the benefit of gentlewomen seeking secretarial employment.

Since the war I have found 2,378 posts for applicants to the registry, classified as follows:—

Permanent	1,121
Temporary during War . . .	571
Temporary	686

I give these figures to show that my experience has been fairly wide, and I would mention just a few of the positions obtained by those who have passed through the registry. There are,

of course, many grades of work—(1) the highly-trained organising secretary, (2) the private secretary, (3) secretaries to heads of big merchants' offices, bankers, etc., (4) the more ordinary shorthand typist in commercial offices, (5) the accountant capable of supervising a department, (6) the book-keeper working under the accountant, (7) the indexer, (8) the tracer, and also the posts for (9) the vast army of clerical workers—by which I mean those who are only doing handwriting, either in connection with insurance work or the War Loan, or work of a similar nature.

Let me give you a few instances. In the very early stages of the war many new spheres of work were necessarily opened to women, both in the commercial world and in many Government Departments. So much extra secretarial help was required by hospitals, war societies, and other new organisations. I was able to introduce the first woman to be admitted into one of the largest insurance offices in the City at a commencing salary of £150. Now she is at the head of a department of sixty-two girls and women—shorthand-typists, clerks, and book-keepers, and I am told by one of the directors that they consider the lady who had been put in charge is simply "doing wonders," and that in every department of this huge firm the women and girls have won golden opinions. One society—and I may add a woman's society—which is doing public work in connection with the agricultural question, started with an organiser at a salary of £300 a year. The Government offices, too, in spite of much criticism as to salaries, have applied to me for workers to fill really responsible positions, and have offered salaries varying from £2 10*s*. to £4 a week; and one applicant, with exceptionally good languages, is now receiving £5 a week. More than ever before have I been asked to supply secretaries to go abroad, and have filled positions in Madeira, Madrid, Alexandria, Copenhagen, Valparaiso, The Hague, Russia, Sweden, Berne, and Aden, and in each case the salaries have been good.

Naturally many of the students have passed on from their first positions to more responsible and remunerative ones, showing the value of experience added to training. One is now the secretary of one of the largest of our hospital organisations; another is engaged on very confidential war work at a salary of £156 a year; another pupil, who started in a position at the War Office, has now been transferred to a special department, and is receiving a salary of £4 a week. I might add that I was asked to release my own private secretary at a day's notice for work in the Prime Minister's "Garden Suburb."

I might also quote from some of the letters I have had giving details of the different positions held by educated women, and showing how much their work is appreciated.

One says:—

"To-day I have been promoted to a position which has never been held by a woman before. The Chief of the Section sent for me, thanked me for getting out the balance correctly, and told me that my work was 'better than most women's, and as good as many men's.' This, I am told, is great praise from him."

Another says:—

"I was at a House of Lords Appeal to-day reporting."

And a third:—

"I know that you take an interest in old 'trainers,' and so I am writing to tell you that I left my post as private secretary to Lord G—— at the end of October to take up work as a company secretary. I have now been there a month and like the work very much, although I have got a lot to learn, and have to spend all my free time reading up about company procedure, etc.

"I get £192, free of tax, which I suppose amounts to about £215, and I have very nice hours, 10 to 5.30, and on Saturdays till 12. I have a nice office all to myself, and all my filing and copying of letters is done for me. I am really taking the place of two men, and am quite a proper *dilutée*. I attend the Board meetings of all the companies, and read the minutes, etc., and I keep the entire accounts of one company."

I think, perhaps, what would interest you most now would be to trace the history of women's work, especially in this branch, since the beginning of the war. I am sure everybody connected with women's work will remember how thousands of workers were thrown out of their positions in, I may almost say, an hysterical fashion by their employers, and we were faced with the grave difficulty of finding fresh openings for those thus dismissed. Even in that crisis I felt quite sure that the thoroughly trained would soon be able to return to their own profession with, if possible, better salaries—and happily in this I was right. I would again point out that the lesser trained or half-trained were the last to find positions.

I am only emphasising this fact to prove the necessity and wisdom of training, and to show you of how much greater value the trained worker can be to her country than the untrained.

I think you would all feel this, too, had you,

as I have, come into contact with the sad cases of elderly educated but untrained women, and been so intimately connected with the special conference which was called to discuss and formulate schemes for their benefit. The report lately issued on this subject should serve as a warning to the present generation.

Then came the next stage—a demand for women to take the place of men going to the Front, and there was an epidemic of short trainings of all kinds. The most immediate need was to help to fill the places of those who had joined the Forces, and so carry on without a break the work they had been doing and had, perforce, to leave; and every nerve was strained to find women and girls ready and willing to offer their services. Short trainings were arranged, which have undoubtedly been of some value, though their *permanent* benefit to the world of commerce is questionable.

Amongst the many schemes at that moment there was one which has really been helpful, especially to the banks, *i.e.* the short training in banking work given under the auspices of the Society for Promoting the Employment of Women, to enable those with special aptitude for figures to step into the breach caused by those called to the Front. Those who had the training were able to show that the rumours that the girls and women who flooded the banks were unsatisfactory arose from the haphazard methods of selection, which seemed to be based on the view that, as women had not worked in banks before, they must all be equally useless, and consequently no attempt should be made to sort the suitable from the unsuitable—the able from the helpless. When the weeding-out process began, it naturally took some time. In this connection, I would quote from a letter from one of our leading banks:—

"Should National Service be introduced many vacancies for ladies will certainly occur, and probably it would be wise to continue the classes for a little while longer, as your pupils, I am sure, will be in strong demand if compulsion is adopted."

As I was anxious to know how many women were now being employed altogether in our leading London banks, I approached the managers and, through their courtesy, received the following statistics. Of course, I cannot mention any names, but the numbers are as follows:—

In A . . .	1,612	Engaged since the outbreak of war, with the exception of perhaps 6.
In B . . .	1,110	Only since the outbreak of war.
,, C . . .	986	Ditto.
,, D . . .	740	Ditto.
,, E . . .	550	50 before the war, 150 now engaged permanently, 400 only since the outbreak of war.
,, F and G .	14	Only since the outbreak of war.
,, H . . .	6	3 only since the outbreak of war, and 3 before that time.
,, I . . .	4	Only since the outbreak of war.

I might also add the following comparison taken from an article in the *Times* of the 6th of this month, which shows that in banking and finance 9,500 women were employed in July, 1914, as against 37,000 replacements by October, 1916.

I must here pause and dwell for a moment on the need for efficiency, which training as a groundwork alone can give. After the war it will be even greater, because it will be a question of the survival of the fittest, and it is only the "fit" who can hope to raise and uphold the standard of work. Therefore, because of the *future* as well as of the *present*, we must urge the necessity of careful training, which alone can make work really valuable.

In my work, which is by no means confined to the secretarial profession, I naturally come into contact with many different degrees of *efficiency* and *inefficiency*. What seems to me the greatest drawback to attaining *efficiency* is the desire for, or perhaps it may even be the necessity of, earning long before the would-be earner is at all ready for her work. Technical subjects are so often started before the general education is completed, and though—and this applies more especially to secretarial training—greater mechanical speed may result from beginning very young, yet this is but a surface efficiency, and does not stand the test of time.

If we wish women's work to have the firm footing it deserves, we must, one and all, fight the growing tendency to snatch at any opening in order to help in the present crisis. We have to look to the future, and we shall help our country just as much, if not more, if we are able to persuade those who can give up time and money to work steadily at whatever profession they wish to enter before joining the ranks of the wage-earners. It is by *efficiency* that we can hope to prove our value in the world of work.

I think the parents still need educating and imploring not to allow the advantages of the immediate present to weigh against the far greater advantages which await the efficient worker in the future. They must remember that a smattering of either education or technical training is of little value.

As regards the actual training for the profession we are discussing, I endeavour to make my pupils self-reliant from the beginning, and to look upon their "training" as part of their life's work; I try to inculcate the idea of loyalty to their future employer; in fact, the head of the Pupils' Department is looked upon almost as an employer, for all work passes through her hands from the very commencement of the training. In this way the pupils are taught to regard their work as "real work," and to be careful, accurate and neat, and never to think "anything will do." I find that this answers splendidly, for it teaches them to become very critical both in regard to their own efforts and the work of others.

I also emphasise the necessity for adding to the curriculum the technical study of foreign languages, and, if possible, their shorthands—in this respect we, as a nation, do not shine. Book-keeping, too, is a very useful and necessary subject, not only for itself and for the use it may be put to either commercially or in the home, but also as an excellent mental training in method and quickness.

Another point in the training is that as soon as pupils attain to any speed in shorthand I expect them to rely upon themselves entirely and to set about their transcripts—*i.e.* the transposing of their shorthand notes to the machine—in a prompt and businesslike way. I also train them to keep their papers tidy in a very small space, and to arrange their work methodically.

Further, I do not approve of large classes for the initial stages, three or four being a good number, but to have some competition is wise; it is also necessary to show judgment in the selection of those who work together, for it does not do to have a very quick learner with a slow one, who, however, in the long run may do just as well if not disheartened.

I could speak in much greater detail about this part of the training, but I do not think such technicalities would be interesting to my hearers, so I have only given a broad outline of what I have found to be a good system for those entering upon their professional career.

"The future depends on the present," as Professor Gilbert Murray said in a delightful address given to young girls, and a great future lies before the younger generation. It is our duty, therefore—the duty of the older ones—to give the young full scope to develop their powers and their talents, not only for their own good, but, above all, for the good of their country.

It is then absolutely essential that all would-be workers should set themselves a high ideal of efficiency and not be content with mediocrity, for how can an employee expect consideration from an employer for indifferent work?

Hitherto we have had to fight against underpayment of workers; at the present day a new danger has arisen, that of the overpayment of *unqualified workers*, who are encouraged to set a false value on themselves and are bound later on to suffer when this crisis through which we are living is over.

In conclusion, I would again ask all who wish to rank among the workers of our day to think over well the work to which they feel most attracted, and then to take absolutely the best trainings available to fit themselves for the careers they have chosen.

I know we have the reputation of taking a long time to wake up, but, as I was told the other day, when we do wake up, it takes a tornado to stop our rush. May this apply to the influx of demands for training!

DISCUSSION.

SIR ROBERT A. HADFIELD, F.R.S., in opening the discussion, said the subject with which the paper dealt was one that appealed very intimately to a busy man like himself. No one suffered more than a busy man from the incompetence of his shorthand writer. Almost without exception the applicants for shorthand positions were not sufficiently trained, and there was plenty of room for ladies who would make themselves competent in the art. Competency, in his opinion, meant the ability to take down shorthand correctly at 150 to 160 words a minute. He could write shorthand himself at about 80 to 100 words a minute, and he drafted out a good many of his proofs in shorthand, but that speed was of no use to an extremely busy man for dictation purposes. He urged on the author the desirability of impressing on her pupils the necessity of getting up a high speed. It was just as noble to be a good shorthand writer, and to help busy people to do their work, as it was to do many other things which appeared to be of higher value. He was afraid also that people in England had a prejudice against a typewritten letter, and he hoped one of the results of the paper would lead to a better understanding on that point. A few years ago

it was considered rather an insult for a person to receive a typewritten letter on a personal matter; but he himself would much rather receive a typewritten letter than a badly written one, because it was impossible to read the latter. America was not so prejudiced in that respect, and he believed the President of the United States personally used a typewriter for his correspondence. The author had not referred to one subject which was almost as important as that of shorthand and typewriting—namely, the art of making a correct *précis*. That was an invaluable help to a busy man. Every morning he received a large number of special letters, statements and reports, which he had not time to go through in detail, and it was simply invaluable to have a good secretary who could grasp the ideas in them and briefly put them into *précis* form. Women who could do that class of work would be able to command much higher rates of salary. Personally he was only too pleased to pay the highest rate of wage to competent people, but it was very annoying when he did so not to get the service expected. It led to bad temper on the part of everyone concerned, which was not at all dignified, but the poor shorthand writer and typist had to get used to it. The better service she rendered, however, the less disturbance of temper on both sides would result.

THE CHAIRMAN (Lady Emmott) said that although notices had appeared in the press in connection with the National Service that applications were not yet to be made for employment, certain people had applied, whom she had seen at Mrs. Tennant's request, and she had been distressed at the number of people who were very keen and anxious to do something for the country and who, when asked what they could do, said, "I will do anything." There was nothing so fatal as that, because one knew at once that the applicant must be inefficient. It would be very much easier if people knew definitely what they could do.

MR. J. QUINN inquired if the author had ever thought of any way in which she could bring home to the powers that be in the elementary educational world how they could qualify, in ordinary educational matters, the young people that intended to take up secretarial work. For the last quarter of a century he had had a good deal to do with the training of the young, and the great conundrum with which he had been faced was the lack of fundamental elementary education on the part of students. Sir Robert Hadfield had asked for shorthand writers who could write 150 or 160 words a minute, but it would take five years for 75 per cent. at least of the young people who took up the system of secretarial training to do so in view of the amount of general education that they possessed, and at the same time to develop their all-round abilities. He desired to emphasise the necessity first and foremost of a proper training in the English language. If a student thoroughly understood her mother tongue, could speak it and spell it, and define it correctly, that, combined with a fair store of general knowledge, was infinitely better as a preliminary training than any amount of speed practice in shorthand. Those responsible for the education of the young should, in his opinion, devote much more attention to grammar, composition, spelling, and *précis* writing. Out of 20,000 students that he had trained not 1,000 were fit to go right on to their subsequent training without constant attention to simple elementary English. If the training were carried out in the way he had suggested, he thought it would be much more effective and much shorter.

MRS. HOSTER, in reply to questions asked by two ladies in the audience, said she did not as a rule take any girl under eighteen years of age to train for commercial work; but since the outbreak of the war she had taken a few of seventeen. The lowest standard she would admit into the office was a high school education, but unfortunately that was not always a very high standard. She always impressed upon the more highly educated girls that it was more necessary for them to be technically competent, otherwise they would lower the standard of women's work. The less educated girls might type more quickly, but they would not win in the long run because their speed alone would not help them; but there was a tendency, especially among some of the college girls, to think that education would carry them through without technical speed and accuracy. She impressed upon her pupils the necessity of being accurate first and attaining high speed afterwards, because it was impossible to attain to the high speeds without a thorough groundwork. Mr. Quinn had to take pupils who could not have the same knowledge and insight into work and help their employers as those who had had a proper education. Nevertheless, Mr. Quinn had achieved wonders, considering the material at his disposal. Then she had been asked how long it would take a student to get up to a speed of 150 or 160 words a minute. That was absolutely a matter for the student herself. She expected a student to attain a speed of at least 100 words a minute in six months; a good many went up to 120 and 130 in that time, but that was exceptional; and there was no reason why at the end of nine months or a year of practical work the student should not do 150 or 160 words a minute. It was no good attempting the high speeds until the lower speeds were absolutely accurate, not only on easy matter but on any matter. The uneducated could not be expected to be accurate in taking down a Parliamentary speech or a speech on any technical subject, because they did not know the language that was being used. They got down the sound in their notes, but the transcripts were simply hopeless. Education was

really the foundation for a good worker in the profession, and it was more and more necessary as time went on. Then she had been asked whether the salaries of the women who took the places of the men were the same. Where they did equal work they received equal pay, but it was unreasonable to expect that girls who had just gone into the banks should receive the same pay as men who had been doing the work for years. She had been told that in a good many cases the girls had started at a much higher salary than the men had, because they were looked upon as temporary workers. In some of the banks one trained man was probably doing the work of three untrained girls, and the same salary would not be paid to them. The banks had been very fair about the salaries. In reply to another question, it was impossible to expect girls at the age of thirteen to have imbibed all the knowledge that was necessary for higher branches of the work. There were, of course, brilliant exceptions; but the mass ended by being just ordinary shorthand typists, for whom it was a great pity there was such a large demand. She wished employers, and the Government especially, would realise that it was far cheaper to pay £2 10s. a week to two competent typists than £1 or £1 5s. a week to six that were incompetent.

SIR HENRY TRUEMAN WOOD thought it was a pity that the discussion had drifted into a consideration of shorthand and typewriting only. If women were to do good work in the world on the special lines indicated by the author, he hoped it would be of a more responsible character. It was a well-known fact that when young men became skilful shorthand writers and typists they were so valuable to their employers that often they would not allow them to pass on to more important work, and the same thing would happen to women. What was really required, whether in a man or a woman, was a well-educated individual who could take up any work to which he had to put his hand. If he wanted a man for responsible and difficult work he would sooner choose a university man from Oxford or Cambridge who had had his mind trained so that he was capable of turning it to any particular business, of which he would very soon learn the routine; and for ordinary commercial work he would much sooner have a young man who was well educated and fairly capable than an ill-educated boy who had been to one of the shorthand-typewriting schools and taught to take down badly in shorthand. For the last few years the increase in the number of girl students at the Society's examinations had been marvellous, and the increase in the quality of their work was equally extraordinary. The number of women who took prizes at the examinations, which was a very good test of ability, was also very considerable. When peace came the question of the survival of the fittest would arise in connection with women, as it had done with men. If they were proficient for the positions they at present occupied they would continue to hold them; if not, they would have to give them up.

MRS. HOSTER said she had desired all through her paper to emphasise the necessity of education first. Shorthand and typewriting came second. Shorthand was a means to an end; it was not the end itself. All the higher posts to which she had referred were not occupied by shorthand typists. High shorthand speed in connection with education was of course invaluable, but it was not everything. Sir Henry had stated that once a young man became a good shorthand typist he did not rise to anything else, but that was not the case with girls, because they had more initiative than the boys. She advised her students to take their first post for experience, and either they would rise in the office or they must leave and obtain a better position in a wider sphere, so that they could use their education, their training, and their experience.

MR. JAMES STEPHENSON considered that shorthand and typewriting should be regarded merely as routine subjects. The object of shorthand was to save time, but commercial education ought to be looked at in a much broader way. He viewed commercial education from the point of view of an engineer and regarded a business undertaking as a machine. It was necessary first of all to know everything inside the business concern, such as book-keeping, commercial correspondence, and office organisation. Then it was necessary to look outside the concern, and study commercial law and subjects which gave vision to those in charge. It was impossible for this country to extend its trade and become the greatest commercial nation in the world without vision, and that would never come from shorthand and typewriting. It could only be obtained by studying what our competitors were doing, and that involved the acquisition of foreign languages, which he regarded as a most important qualification. He also advocated an alteration of the present matriculation examination, in which the compulsory subjects were, firstly, English; secondly, a good knowledge of mathematics; and, thirdly, a science or an ancient language. Was it not feasible that the syllabus should be altered so that it was possible for a student to take science, an ancient language or a modern language? In that way the universities would be encouraging the study of foreign languages, and would place commerce upon the same basis as arts and science.

MRS. NATHANIEL L. COHEN hoped that, as the education of the country was about to be revolutionised, the new Minister of Education would be urged that such a system should be adopted that the minds of the people would be so trained as to make them powerful and elastic, so that they could always cope with the unexpected that was always turning up.

MISS MARGARET FRODSHAM pointed out that, as the author received only girls who had had a high school education, she had had the advantage of dealing with pupils who had already had trained teachers to teach them. The elementary education of the country was at present in such a condition that large numbers of governing bodies continued to appoint elementary teachers who fulfilled the statutory regulation that they had reached the age of fourteen and had been vaccinated.

MR. G. F. PITTAR thought that in a great many cases much time would be saved if commercial men dictated their correspondence straight to the typewriter, without the use of shorthand. He had personally found that of the greatest assistance, much time being saved in correcting the manuscript, while the principal had not to wait to sign his correspondence. Before the war he was acquainted with an office in which there were a certain number of both women and men typists, and the principals preferred to dictate to the latter rather than to the former because if they met with any difficulty they came and asked about it, whereas the lady tr anscribed what she had on her notes, whether it was sense or not.

MRS. HOSTER agreed with the last speaker that it was invaluable there should be in every office one or two typists who could quickly rattle off a letter that was dictated to them straight on to the machine without making any mistakes.

On the motion of the CHAIRMAN, a vote of thanks was accorded to Mrs. Hoster for her pap er, and the meeting terminated.

DRAWN-WORK INDUSTRY OF SWATOW.

While the export trade from Swatow in drawn work had begun to decline before the outbreak of hostilities in Europe, the war has seriously affected the local industry, as European countries were Swatow's best customer for drawn work, and it is but natural that the demand therefor (such goods being in the nature of a luxury) should fall off sharply in the belligerent countries. Recently, however, the industry has showed signs of recovering.

As the term signifies, drawn-thread work is openwork done on grass or other cloths by drawing out threads or by cutting holes in the cloth, and then working the open spaces with cotton thread into floral or other designs. The manufacture of drawn work was first taught to native women in the Swatow district by missionaries some twenty-five years ago, and the industry has flourished ever since. It is believed that the patterns and designs came originally from Europe and Mexico.

In the beginning the output was insignificant and the wages small, each female worker earning about 5*d*. a day. Gradually more women took up the work, new patterns were introduced, and the skill of the workers became greater, some of them earning as much as 1*s*. per day. The work was first done in Swatow, but as it was such that it could be done in the homes women in the interior took it up. Naturally, the output increased and competition followed, with the result that the workers' wages fell. A first-class worker now receives only 6*s*. to 10*s*. per month. The work is at present carried on chiefly in the neighbourhood of Swatow and in the Kityang district.

According to a report by the United States Consul at Swatow, the grass cloth that is used locally for drawn work is made from ramie grown in the Yangtse River valley. There are two kinds, the finer of which is produced in Hsin Huei and exported from Canton, and the coarser quality is manufactured in Kityang. The Canton cloth is woven on foreign looms, and comes in bolts of 32 in. by 20 yards or 16 in. by 40 yards. The Kityang cloth is made on Chinese looms; the bolts measure 15 in. to 22 in. by 20 yards. The cotton thread used in working up the designs is foreign spool thread (chiefly British) and crochet thread in balls.

Most of the drawn work exported is embroidered. Embroidery is an old native industry, but the methods now in use are modern. This work is done exclusively at Chaochowfu, a large city about twenty-five miles from Swatow. The thread used is either plain or mercerised cotton. The natives engaged in embroidering receive very scant wages—1¼*d*. to 2½*d*. a day. The annual value of the exports of drawn work from Swatow is estimated by dealers at over £10,000.

INDIAN LEMON-GRASS OIL.

The chief commercial centre for lemon-grass oil is said to be Trivandrum, Travancore, and the exports are made from Cochin and Quilon. The shipments to all countries in the fiscal year ended March 31st, 1916, were 30,976 gallons (value £37,200), an increase of 3,561 gallons over 1914–15. Exports to the United States in the half-year ended June 30th, 1916, were 37,883 lb., valued at £3,800, and in the calendar year 1915 they were 88,480 lb., valued at £9,700. The price in Cochin at the end of June was 30*s*. per dozen 24-oz. bottles.

Obscurity prevails as to the botanical sources of East Indian lemon-grass oils, but they are generally stated to be derived from *Cymbopogon citratus* and *Cymbopogon flexuosus*. According to a report by the United States Consul at Madras, the former is a native of Bengal and is largely cultivated all over India, but the oil distilled in the Malabar coast is derived principally from

C. flexuosus. This plant grows plentifully in Travancore, especially on the slopes of the mountains to the north of Anjengo. The hill-sides are said to be fired in January to burn down the old and useless grass. Six months later the fresh crop is ready to be cut; by that time the countryside is dotted all over with furnaces and stills. During July, August, September, and October operations are continually maintained, but there would appear to be no second crop. In a few cases Europeans have established distilleries on an improved plan.

The moplas (native gatherers) are said to recognise twenty-seven forms of the wild plant, of which five only are of commercial value and one is cultivated and never flowers. The most interesting feature of lemon-grass oil is the large percentage of citral that it contains. This has been variously stated at 70 to 80 per cent., and inferior or adulterated samples 40 to 50 per cent. It is employed in the manufacture of artificial perfumes, such as the violet, known as ionone, and like all the grass oils is utilised mainly in perfuming soaps. An important use to which it is applied is in the preparation of furniture polish. The production of lemon-grass oil in South India on a commercial scale is an industry of comparatively recent growth.

ENGINEERING NOTES.

Hydro-electric Power in the Commonwealth and in New Zealand.—The Minister for Public Works has referred to the Public Works Committee of New South Wales the adoption of the following schemes for the utilisation of electric power on the Murrumbidgee River, at Barren Jack Dam and at the Snowy River. In constructing these particular dams provision had to be made to allow for a continuous outflow over the dams, and engineers considered this wasted power could be economically harnessed for generating electrical power. The estimated cost of the second scheme, outlined in the report, would amount to £100,000 for providing the construction of plant, transmission lines, and distributing houses. The power generated would approximate 8,000,000 units per annum. The Minister indicated that the annual expenditure on such a scheme would amount to £9,095, and the revenue £11,686, leaving a net profit of £2,591. This might not be the immediate result, but was an estimate for a few years after the scheme was in operation. The proposal related to the requirements of towns on the south-west tableland—Goulburn, Yass, Harden, Cootamundra, Junee, Wagga, Gundagai, and Tumut. The second scheme was that of works on Snowy River. The Minister, Mr. Cann, said this was far more costly and pretentious than the Barren Jack scheme, and had infinitely greater possibilities, but settlement had not yet taken place, and the power generated would have to be distributed over a much greater distance. The proposed dam on the Snowy River, about a mile below Jindabyne, would be 148 ft. high, and would have a capacity for 26,000,000 cubic feet of water. The power-house would develop an average load of 100,000 kilowatts, with a maximum of 125,000, and there would be available at the point of delivery 750,000,000 units of electricity per annum, as compared with 8,000,000 in the Murrumbidgee scheme. The transmission line for the power-station would be 210 miles in length, and would bring the power right into Sydney. It was anticipated, however, that a large amount of power would be used on the south coast for electro-metallurgical and other processes. This would enable New South Wales, better than any other State, to compete with electric process manufactures in the old world, such as the treatment of ores, etc. The estimated capital cost was £5,000,000. The annual cost, including interest, etc., would be £361,173, equivalent to £2 3*s.* 5*d.* per h.p. per annum; and if all the units were sold at ½*d.* per unit the éstimated surplus would be £37,777. Mr. Cann outlined schemes of a like nature in regard to hydro-electric development on the Shoalhaven River, Cataract, and Cordeaux Rivers, Gilmore Creek and the Tumut River. These were all referred to the Public Works Committee. As to the daughter State of Tasmania, the *British Australasian* says, in view of the increased demands which it is expected will be made by metallurgical undertakings upon the Government Hydro-Electrical Department for power, it is understood that steps are being taken to obtain data respecting Lake St. Clair, situated some twenty-five miles westerly from the Great Lake (*see* "Engineering Notes" of July 28th, 1916). Lake St. Clair, it is stated, has a surface area of about thirty miles, and varies in depth to 600 ft. If anticipations are realised, a fall of approximately 1,000 ft. will be obtainable when this supply is harnessed. The general programme of the Tasmanian Government in connection with hydro-electrical power for industrial purposes has been outlined in a Ministerial statement already published. Unofficial estimates have been made giving the present nominal capacity of the existing works at the Great Lake as equal to some 10,000 h.p., and the approximate total which may ultimately be developed as up to 100,000 h.p. With reference to New Zealand, Mr. J. Orchiston, M.Inst.C.E., Chief Engineer of Telegraphs, New Zealand, in a letter to the *Times*, points out that the South Island of New Zealand is richly endowed with magnificent water powers, many of them coming right down to the water's edge in the sounds on the south-west coast. Water powers ranging up to 40,000 h.p. can be obtained at an expenditure of from £5 to £10 per h.p. for the hydraulic

development, and in many cases no transmission lines would be needed, as the power-station could be located alongside deep water. Heads ranging from 500 ft. to 1,000 ft. or over are procurable, so that the conduits, piping, water-wheels, foundations, etc., need be only of minimum dimensions for the output developed. In some cases less than a mile of piping is all that would be required to utilise a head of 1,000 ft., with a constant flow ranging up to 500 cubic feet per second, fed from glaciers. By the construction of a tunnel about five miles in length, mostly through granite, the whole of the discharge of the Te Anau Lake, covering an area of 135 square miles, could be diverted to one of these sounds, giving an effective head of nearly 600 ft., and a constant discharge exceeding 12,500 cubic feet per second. Few countries can so easily provide a power of such dimensions (approximately 700,000 h.p.) at the edge of a deep-water harbour. There are numerous other water powers available inland, ranging up to 100,000 h.p., which could be developed at a very low cost, but they are at present not conveniently located for transport purposes, and they would involve fairly long transmission lines.

Heating Dwelling-houses.—A writer in the New York *Electrical World*, who has been carrying out experiments in the heating of dwelling-houses by means of coal and electricity, has come to the conclusion that, with electricity at $\frac{1}{4}d.$ per kilowatt-hour, it is from 25 to 50 per cent. more expensive than for coal at 25*s.* per ton. At $\frac{1}{2}d.$ per kilowatt-hour, electricity is two and one half or three times as costly. These figures are borne out by theory, which indicates that the 10,000 B.Th.U. in a pound of coal cost $\frac{1}{12}d.$, while in the form electrical energy the 3,413 B.Th.U. in 1 kilowatt-hour will cost $\frac{1}{4}d.$, making the current roughly five times as expensive; then allowing for a furnace efficiency of 40 per cent., which is fair for the ordinary furnace, the current should prove twice as expensive. A hot-water radiator system was employed in both cases. Some interesting figures, also on the same subject, were given recently, in a paper by Mr. W. B. Smith read before the Greenock Electrical Society. The author said that in actual heating value electricity is seriously handicapped when compared with coal and gas. From each unit of electrical energy only 3,410 B.Th.U. can be produced, so that at $\frac{3}{4}d.$ per unit, one pennyworth of electricity gives 4,550 B.Th.U. One pennyworth of gas at $2\frac{5}{11}d.$ per 1,000 cubic feet has a heat value of about four times this amount; while for coal at 25*s.* per ton the same cost would yield 105,000 heat units, or over twenty times the number of B.Th.U. But the excellent efficiency of electricity for heating enables it to compete in point of cost with gas at least, and, although more costly than heating by coal fire, its other advantages would certainly recommend it in preference to the coal fire.

CORRESPONDENCE.

THE BEN-I-ISRAEL.

In connection with the paper of Sir Thomas Holdich, I am somewhat surprised to note that he is inclined to recognise the Armenians as some of the lost tribes of Israel and of strong Hebraic appearance.

Is it not agreed that the Armenians were of Phrygian descent (in other words, Iranians), and had advanced far east by the middle of the fifth century B.C.?

As far as concerns those in the districts of Aleppo, Carchemish and Haran, or South-Western Armenia, there would probably be many descendants of the old Hittites, who are said to have had a Mongolian origin, and indeed in the old monuments are represented as wearing pigtails. I have seen somewhere a profile of a Hittite wife of an Egyptian Pharaoh which strongly resembles the women of this region. The children there often are like young Italians. The hair of the inhabitants is frizzy and dark (not black), very unlike their neighbours the Syrians. They have fine large eyes, mostly brown or hazel, and clearly marked eyebrows and long eyelashes, while the nose is not hooked but has a prominent bump in the middle.

Although in customs they strongly resemble the Jews and Mohammedans, and indeed freely do business with the former, and even enter into partnership with them, yet they avoid social intercourse as far as possible, and are very strongly opposed to marriage with them.

About what time are they supposed to have adopted the typical ending of "ian" to their names? I have never come across it in Armenian names in the history of old Egypt.

HYLTON B. DALE.

Radleigh,
Village Road, Enfield.

OBITUARY.

HERBERT OAKEY.—Mr. Herbert Oakey, whose death took place on November 13th last, in his sixty-sixth year after a long illness, had been a member of the Royal Society of Arts since 1899.

Born in 1851, Mr. Oakey, at the age of sixteen, entered the business of his father, John Oakey, in Blackfriars Road. Later on the firm was transferred to Westminster Bridge Road, where the well-known Wellington Mills were built. In 1892 the firm was formed into a limited company under the title of John Oakey and Sons, Limited, and

they carried on a very extensive business in the manufacture of emery and black lead, rubber knife-boards, knife polish, silversmiths' soap, and kindred goods. Mr. Herbert Oakey became managing director and chairman of the company, holding the latter position up to the time of his death.

NOTES ON BOOKS.

JOSEPH PENNELL'S PICTURES OF WAR WORK IN ENGLAND. London: William Heinemann; Philadelphia: J. B. Lippincott & Co. 6*s.* net.

Some time ago Mr. Pennell received permission from the authorities to visit the principal munition works in England with the idea of making an artistic record of the mighty industrial effort which is now being made throughout the country. The result of his mission was seen in the remarkable exhibition of drawings which was held in the Guildhall in December last. Of those drawings fifty-one are now collected together and given permanent form in the volume before us.

The first fifty pictures are of subjects directly connected with the manufacture of munitions. They represent various stages in the making of shells, the forging of big guns, the building of ships, etc. Such scenes, both within and without the works, with their extraordinarily bold effects of blaze and blackness, are exactly congenial to Mr. Pennell's genius, and this series of drawings is as fine a piece of work as he has ever done. Taken collectively, they give a wonderful idea of the feverish effort being made by modern science to cope with the appalling demands of modern war.

The subject of the last drawing differs from those of the rest. It is the scene visible every night from the artist's window—the shot-tower standing out black against a lattice-work of searchlights. In the opinion of Mr. H. G. Wells, who writes a preface to the volume, it is the only commonplace subject amongst them all. Few people, we fancy, will endorse this verdict, for the scene is intensely dramatic, and deserves to be put on record as much as any of the others—even though most of us would give anything, like Mr. Pennell himself, never to see it again.

THE REAL GERMAN RIVALRY. By Sir Swire Smith, M.P., LL.D. London: T. Fisher Unwin, Ltd. 1*s.* net.

Sir Swire Smith has been long and honourably known for his services on behalf of technical education in this country. Thanks to the work instituted by him in his native town, Keighley at one time sent more exhibitioners to the Royal Colleges of Science and Art at South Kensington than any other city or town in the kingdom. So remarkable, indeed, was its success that Professor Huxley once declared that Keighley had gone far to solve the technical education problem; and the late Duke of Devonshire, when speaking of the National Association for the Promotion of Technical and Secondary Education, said that, in brief, its object was to induce the rest of the country to follow the example of Keighley.

It will be no surprise, then, for those familiar with the work of Sir Swire Smith to learn that, in the struggle for trade which will come at the end of the war, he sees the salvation of this country in technical education. Most people are at one with him in desiring to see every possible improvement in this direction, and in his efforts will only wish him more power to his elbow; but some of his arguments do not seem to be quite consistent with others. For instance, if commercial superiority depends upon technical training, and if we have been so immeasurably inferior to Germany in this respect for the last forty or fifty years, how does it happen that British exhibits at the Brussels Exhibition were so superior to those of other countries, as Sir Swire Smith says they were? It will hardly do to accept his major premiss for one part of his argument, and at another to declare that our superiority is due to Free Trade.

Again, we do not think that his advocacy of the cause of technical education will gain much from his criticism of our system of liberal education. We have all heard of the boy from the great public school who was of no use to the manufacturer because he knew nothing of drawing, designing or machinery; and who was rejected by the business man because he did not know book-keeping and could not correspond in French and German. The aim of liberal education is obviously quite different from that of technical education—each has its separate function to perform; and while we are far from denying the possibilities of improvement in both, we think that no good will be done by advocating the claims of one at the expense of the other.

With much of what the author says in his section dealing with "To-morrow" we are in cordial agreement. The mass of the people now recognise, as they never recognised before, the value to the country of the skilled mechanic and the highly-trained chemist and engineer. If the war has taught them nothing else, it has taught them this, and there are already hopeful signs that in the future more care and money will be devoted by the authorities both to technical training and to scientific research of the highest kind.

To all interested in the industrial future of this country, we commend Sir Swire Smith's book, for they will find in it much to stimulate their interest, and not least in those passages in which their views may differ from his.

GENERAL NOTES.

Belgian Relief.—Readers of the *Journal* may be interested to learn that the Foreign Office have ordered 5,500 reprints of the issue of January 26th, 1917, containing Mr. W. A. M. Goode's paper on "Relief Work in Belgium," to be used for propaganda purposes.

Silkworm Production in France.—Although the production of cocoons last year in France was slightly greater than that of the previous season, the latest official returns show a considerable decrease in the silk harvest since the outbreak of the war. According to these figures, the total number of silkworm rearers in that country was 52,756 last year, as compared with 48,327 in 1915 and 83,823 in 1914. The quantity of eggs hatched in each of these years was 60,305 oz. (of 25 grammes), 49,132 oz., and 108,943 oz. respectively. The total weights of raw (live) cocoons produced each year was :—

	Kilograms.	English lb.
1916	2,797,295	6,167,035
1915	1,738,504	3,833,401
1914	5,067,392	11,173,599

The average yield of silk cocoons per ounce of eggs during the last three seasons was :—

1916	46 kilogs	380 grammes.
1915	35 ,,	384 ,,
1914	46 ,,	514 ,,

The average prices realised last year were 4·35 francs per kilog, as compared with only 2·45 francs in 1915 and 4·01 francs in 1914.

Dried Pepper Industry in Hawaii.—The correspondent at Honolulu of the United States Department of Commerce reports that many inquiries have recently been received there concerning the common small red Hawaiian peppers. Since a quarantine was placed on several fruits and other products of the Hawaiian Islands by the California authorities, on account of the report that the Mediterranean fly had infested some of the products of the islands, the pepper is no longer grown there on a commercial scale. Practically every Hawaiian has pepper plants around his house for home use, but none are now grown for drying or exporting. These peppers are very easily raised all over the islands, and if a good market could be found for the dried product the Territorial Marketing Division, conducted under the supervision of the United States Experiment Station at Honolulu, believes that the industry could be established on a profitable basis. An official of the Territorial Marketing Division states that an attempt was made by the division a short time ago to establish the dried-pepper industry at Honolulu, using Anaheim Chili pepper, but without result. Peppers can be shipped in a dried state to the United States; but there is a quarantine against the fresh product, owing to its susceptibility to the melon fly. The producer would have to get about 8½*d.* a lb. for the dried product f.o.b. Honolulu to make it a paying business.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

February 28.—Francis A. Hocking, B.Sc., Pharmaceutist to the London Hospital, "The War and our Supply of Drugs." Robert Hutchison, M.D., F.R.C.P., will preside.

March 7.—James Harris Vickery, LL.B., "German Business Methods."

March 14.—Dr. J. Augustus Voelcker, "Fertilisers and their Supply in War Time."

March 21.—G. W. Jones, "Colour Printing and some Recent Developments." Carmichael Thomas, Chairman of the *Graphic* and *Daily Graphic*, will preside.

April 18. — Horace M. Thornton, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

April 25.—Sir Francis Fox, M.Inst.C.E., "Flour and Bread." Captain Charles Bathurst, M.P., Parliamentary Secretary, Ministry of Food, will preside.

Indian Section.

Thursday afternoons, at 4.30 p.m. :—

March 15.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

April 19.—D. T. Chadwick, I.C.S., "The Future of Indian Trade with Russia and France."

May 17.—Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

February 27. — Alfred Bigland, M.P., "The Empire's Assets and how to use them." W. A. S. Hewins, M.P., will preside.

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

DR. M. HORN, "The Economic Development of the Belgian Congo."

PROFESSOR WILLIAM RIPPER, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency."

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m.:—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

Syllabus.

LECTURE I.—MARCH 5.—The spirit of memorial design—Art sacrifice and utility—The matter of inscriptions—Development of various monumental types and conventions—Praying figures—Canopied monuments—Mural tablets—The placing of monuments in buildings—Historical sketch.

LECTURE II.—MARCH 12.—The designing of modern monuments—Architect and sculptor—Influence of setting—Adoption of historical styles—Choice and treatment of materials—Brass, stone, marble, wood, lead—Lettering—Heraldry—Emblems and symbols—Christian feeling in memorial art—Crosses and Calvaries—The churchyard.

LECTURE III.—MARCH 19.—Equestrian figures—Group memorials—Public school, regimental and civic monuments—The War memorial—Teuton *versus* Latin spirit in design—The Christ of the Andes — Columns and arches — Buildings and bridges—Monumental art and town planning.

HOWARD LECTURES.

Monday afternoons, at 4 p.m.:—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies: (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market." Two Lectures.

April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 26 ... East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Mr. T. H. S. Biddulph, "The Native States of India in their relation to the Paramount Power."

TUESDAY, FEBRUARY 27 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. A. Bigland, "The Empire's Assets and how to use them."

Arts, Royal Academy of, Piccadilly, W., 3.30 p.m. Mr. C. Dodgson, "Old Engravings."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. E. Dalby, "The Strength and Structure of Metals." (Lecture I.)

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7 p.m. Mr. J. Shepherd, "Some Points in Connection with Engineering Specifications."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. E. W. Mellor, "A Chronological Survey of some Landmarks of Ancient Egypt."

Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Major A. J. O'Brien, "The Criminal in the Western Punjab."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m. Mrs. Blount, "The Yukon River from Source to Sea."

WEDNESDAY, FEBRUARY 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. F. A. Hocking, "The War and Our Supply of Drugs."

Pottery and Glass Trades Institution, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. W. G. Savage, "The Protection of the Milk Supply."

Oriental Studies, School of, London Institution, Finsbury-circus, E.C., 5 p.m. M. de Z. Wickremasinghe, "Ceylon during XVIth and XVIIth Centuries."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor Gerothwohl, "The Entente and the New Humanities."

THURSDAY, MARCH 1...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. J. C. Mottram, "Some Observations on the Feeding-habits of Fish and Birds with special reference to warning Coloration." 2. Dr. D. H. Scott, "The Heterangiums of the British Coal-Measures."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Mr. J. A. N. Friend, "Notes on the effect of heat and oxidation on linseed oil." 2. Messrs. G. T. Morgan and A. W. H. Upton, "Acyl derivatives of paradiazoiminobenzene."

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. S. Prior, "Memorial Art To-day." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. A. Maude, "Russia and its Writers."

Arts, Royal Academy of, Piccadilly, W., 3.30 p.m. Mr. F. M. Fletcher, "Woodcuts in Colour."

FRIDAY, MARCH 2...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. W. H. Godfrey, "Chelsea."

Royal Institution, Albemarle-street, W., 5.30 p.m. Mr. C. F. Cross, "Cellulose and Chemical Industry, 1866-1916."

University of London, University College, W.C., 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture VII.)

Economics and Political Science, London School of, Clare Market, W.C., 8 p.m. Mr. H. Rathbone, "The Wheat Supply of Great Britain."

SATURDAY, MARCH 3...Royal Institution, Albemarle-street, W., 3 p.m. Mr. D. Jones, "The Pronunciation of English at the time of Shakespeare." (Lecture II.)

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 3 p.m. Verhaeren Celebration.

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—February 23, 1917.

Journal of the Royal Society of Arts.

No. 3,354. VOL. LXV.

FRIDAY, MARCH 2, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 5th, at 4.30 p.m. (Aldred Lecture.) LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." (Lecture I.)

TUESDAY, MARCH 6th, at 4.30 p.m. (Colonial Section.) MONSIEUR M. HORN, LL.D. (Brussels), "The Economic Development of the Belgian Congo." A. D. STEEL-MAITLAND, M.P., Parliamentary Secretary, Colonial Office, will preside.

WEDNESDAY, MARCH 7th, at 4.30 p.m. (Ordinary Meeting.) JAMES HARRIS VICKERY, LL.B., "German Business Methods." The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.B., G.C.M.G., K.C., M.P., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COLONIAL SECTION.

Tuesday afternoon, February 27th, 4.30 p.m.; MR. W. A. S. HEWINS, M.P., in the chair. A paper on "The Empire's Assets and how to use them," was read by Mr. ALFRED BIGLAND, M.P.

The paper and discussion will be published in a subsequent number of the *Journal*, though, in consequence of the restriction of paper supplies, there will be some unavoidable delay before they can appear.

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 28th, 1917; ROBERT HUTCHISON, M.D., F.R.C.P., in the chair.

The following candidates were proposed for election as Fellows of the Society :—

Bartle, George William, M.I.Mar.Eng., A.M.I. Mech.E., 27A, Mile End-road, E.

Das, Manmatha Nath, B.A., A.M.I.Mech.E., 19, Waverley House, Kenton-street, Russell-square, W.C.

Edwards, R. Jestyn, Brynawel, Alltwen, Pontardawe, Glamorgan.

Wolseley, Lady, Wolseley, Stafford; and Brown's Hotel, Albemarle-street, W.

The following candidates were balloted for and duly elected Fellows of the Society :—

Bertrand, J. F., Isle Verte, Temiscouata County, Quebec, Canada.

Chrimes, Thomas Edward, R.N.A.S., Holmcroft Wilbury Villas, Hove, Sussex.

Comber, Joseph Forstall, Assoc.Inst.C.E., The Lagunas Syndicate, Ltd., Oficina North Lagunas, Iquique, Chile.

Eckford, Captain George, R.E., The Old House, Milston, Salisbury.

Lewis, Nolan D. C., M.D., Crownsville State Hospital, Crownsville, Maryland, U.S.A.

Loring, Mrs. William Caleb, 2, Gloucester-street (corner of Beacon-street), Boston, Massachusetts, U.S.A.

The paper read was—

THE WAR AND OUR SUPPLY OF DRUGS.

By F. A. HOCKING, B.Sc.,
Pharmaceutist to the London Hospital.

The privilege of reading a paper before the Royal Society of Arts affords an opportunity of presenting this subject from a point of view which has not received much attention from the various writers and speakers who have hitherto taken part in its discussion.

A number of papers have been written by gentlemen undoubtedly highly qualified to give most valuable advice of a botanical, horticultural, and chemical nature, and no aspect of the question seems to have escaped full discussion save one, and that the most important. According to the published reports, little or no attempt appears to have been made to ascertain definitely what drugs actually are employed in the treatment of disease, and consequently there has been a tendency to expend, somewhat uselessly, time, trouble, skill, and technical knowledge, to say nothing of printer's ink, upon unimportant divisions of the subject.

In times such as the present, attention should be concentrated upon those drugs which experience has demonstrated to be actually helpful, and hence necessary, to the treatment of disease, and I submit that the most reliable testimony to the value or otherwise of drugs is provided by the practice of the great general hospitals at which the future medical man or woman receives his or her training in the methods employed in the treatment of disease; for the various methods employed *to-day* in these institutions in alleviating physical suffering are precisely the methods which will be employed in private practice *to-morrow*, when those men and women have graduated from these centres of medical and surgical education.

And, as I have the honour to serve in the largest voluntary hospital in the kingdom, I trust I may be excused if I base many of my remarks upon the practice of the London Hospital, which, with its 17,000 in-patients and 170,000 out-patients annually, affords very valuable and representative data for a discussion such as the present.

It is proposed to divide the subject into three sections and consider :—

1. What drugs were in use before the war, and to indicate to what extent we were dependent upon Central Europe for their supply.

2. The difficulties arising out of the war, and to what extent these have been surmounted.

3. The period after the war.

I.—The Drugs in Use before the War and their Origin.

It may be advisable to remark that in using the term "drug" the reference is not to the forms in which they are administered, but to the original materials of which these latter are compounded. An illustration will make this clear. Cascara bark is the drug; the Liquid Extract or the Tablet is the form of its administration.

It is also desirable to point out that new remedies are often composed of very simple and well-known constituents. Thus the antiseptic solution known as Eusol is made entirely from the familiar substances Boric Acid, Chlorinated Lime, and water.

Our concern at present is solely with the drug, not with the forms in which it is used.

In reviewing the drugs in use before the war it will be convenient to consider them in seven groups.

The First comprises medicinal plants.

Much misconception exists regarding both the importance of the members of this group and the extent to which they are employed, due partly to the fact that the experts who have been consulted, while of undoubted eminence in their knowledge of the botanical characters and microscopic structures of medicinal plants, are not in close touch with actual medical and surgical practice.

Societies have been formed, lectures given, and books written urging, on patriotic grounds, the cultivation of medicinal plants in this country; but one would like to have seen more attention paid to the question as to whether this is necessary, and, if so, to what extent.

"Times have changed" is a trite saying peculiarly applicable to the use of vegetable drugs. Formerly the physician derived his principal, and perhaps more numerous, remedies from the vegetable kingdom; but in recent years a variety of circumstances has contributed to bring about a material change.

New methods of treatment have been devised which do not necessarily involve the use of drugs, such as the employment of Sera and of Vaccines, and of physical agents, as electricity, light, etc. As the Regius Professor of Physics at Cambridge says :—

"We are learning also the virtues of high altitudes, of climates and other natural conditions, as we are discovering more and more new resources in other physical means—in rest cures, passive and active exercises, respiratory gymnastics, electric and ray therapeutics, radio-activity, diathermy, and so forth."

The greatly extended use of substances of definite chemical composition derived from the mineral kingdom or prepared in the chemical laboratory has tended to reduce the use of vegetable drugs, for the constant composition of the former presents great advantages over the often varying constituents of the latter.

For these and other reasons it comes about that, of the large numbers of drugs described in a text-book of Vegetable Materia Medica, some are occasionally prescribed by medical practitioners of a past or passing generation who still adhere to what Sir Clifford Allbutt calls "the blind and formal drug-mongering of the elder tradition in the practice of physic"; some are to be seen only in a museum; some are constituents of the "heal-alls" of domestic medicine; and others are in demand by the patent medicine proprietor who grows wealthy by reason of the childish faith of an all-too-credulous British public.

The list of drugs actually used in the London Hospital in the year 1914, for the purpose of

this paper regarded as a peace year, includes about eighty of vegetable origin.

Of this number some, such as Alkanet Root, are used merely for colouring; others, as Orange Peel, for flavouring; and some, as Orris Root, for perfuming; while a few, as Tragacanth, are employed for pharmaceutical, as distinguished from medical, purposes.

On looking at the geographical sources of the most important, we soon discover that very few indeed are derived from Central Europe.

Several are cultivated or grow wild within the borders of the British Empire; thus:—

Cinchona bark comes from India and Ceylon, as well as, of course, from non-British parts of the world.

Cinnamon bark from Ceylon.

Buchu leaves from South Africa.

Senna leaves from India, and also Egypt.

Quassia wood from Jamaica.

Nux vomica seeds, the source of strychnine, from India.

Castor-oil seeds also from India, as well as Sandal-wood oil.

Ipecacuanha root of sound quality comes from Johore.

Many come from non-European countries outside our Empire, such as:—

Camphor, which is a Japanese Government monopoly.

Cascara bark from the United States of America.

Calumba root from Africa.

Ipecacuanha root from Central America as well as from previously named source.

Rhubarb root from China.

Of those which are supplied by Europe, some are imported from neutral or allied countries—thus, Ergot comes from Russia and Spain, Squill from the Mediterranean shores.

Ultimately we arrive at a short list of medicinal plants, not exceeding eight in number, formerly derived from enemy countries. They are Aconite Root, Belladonna Root and Leaves, Colchicum Corm, Digitalis Leaves, Gentian Root, Henbane Leaves, Opium, and possibly Valerian Root. Of these it is generally admitted that Digitalis grows wild in this country in sufficient quantity for all our needs. And I am informed that very large quantities of wild colchicum corms, *i.e.* meadow saffron, have been gathered in this country during the past two years; hence little difficulty seems to exist.

For opium we are not entirely dependent on Eastern Europe, Persian opium having been for long an article of commerce, and since the outbreak of war Indian opium has been imported for the production of morphine—in fact, the world's supply of this alkaloid is to-day practically all produced from Indian opium.

Gentian root is but one of a number of bitters of equal value; hence any deficiency is not of great importance.

Indian or Japanese Aconite might be used probably to supply any shortage of the European article.

The real difficulties were in connection with Belladonna root and leaves, Hyoscyamus leaves, and possibly Valerian. There may perhaps be one or two others which have a localised use in different parts of the country. The past tense is used because Egyptian henbane tends to render the cultivation of other Solanaceous plants a matter of indifference, and Japanese Valerian Root has been used for the European article.

It is difficult to estimate accurately the real extent of the deficiency because, for instance, while some people bemoan the shortage of English belladonna root, yet others are able to obtain their requirements; thus the London Hospital secured 1 cwt. of excellent root (wild) from Hampshire.

The shortage of belladonna and foxglove leaves cannot be so great as is supposed, for even during the war appreciable quantities of the English-grown products have been exported.

Even if the cultivation of these few plants be necessary, much caution is required. It cannot be stated too often that the demand is and must be strictly limited.

Drugs are, or should be, for the sick only, who constitute, it is hoped, a minority of the population; further, Belladonna, Foxglove, and other essential plants are often poisonous in large quantity; hence medicinal doses are very small.

In view of these two facts, it needs no expert knowledge to realise that a very little over-production will soon render these drugs a glut on the market, and so reduce prices to a non-remunerative level.

Probably we may rely upon the business enterprise of the proprietors of the old-established drug farms of this country to meet in some degree at least the problem arising out of the present situation.

In view of what has been said, it seems that too much attention has been directed to a difficulty which is scarcely so urgent as has been represented; hence, may it not be asked if the energy at present being devoted to growing

medicinal drugs might not be better utilised in the production of foodstuffs?

A Second group comprises about fifteen substances obtained from the animal kingdom. Of these one was exclusively German, namely Lanolin, the fat of sheep's wool—a very useful basis for ointments. With this exception no one country can claim a monopoly of such articles as beeswax, honey, pepsin, and dry thyroid gland.

The Third group comprises the extremely important class of substance known as Alkaloids, obtained from plants gathered from the ends of the earth.

It will be convenient here to call to mind that much has been written and said concerning our real or supposed dependence on Germany for medicinal chemicals, and for the most part the view taken has been accompanied by some exaggeration. It is most undesirable to commit the fatal mistake of underrating one's enemy or competitor, but in avoiding this error it is surely not necessary to fall into the opposite one of unduly depreciating the abilities and resources of our own country. The jeremiads uttered by some would lead us to believe that Germany was the source of all drugs of any importance, and that with the outbreak of war supplies ceased!

In order to correct this extreme view, it is proposed to indicate in this and succeeding groups the more important chemicals used in medicine, and to note very briefly to what extent we were dependent on Germany.

The number of alkaloids or their salts used in the London Hospital in the year 1914 was about fifteen. Of these, seven—namely, Apomorphine, Acetomorphine, Morphine, Codeine, Caffeine, Strychnine, and Emetine—were, and of course are, manufactured in England on a large scale, not merely for home consumption, but also for export to all parts of the world, and we may claim that for both quality and quantity the English products were easily first.

It is true Germany sold these drugs, but it is not easy to determine what proportion was of German manufacture and what of English manufacture bearing a German label, for it is an established fact that the Teuton imported appreciable quantities of these British-made alkaloids.

With reference to Quinine, one cannot claim that English Quinine dominated the world, for it is produced in the United States of America, France, Germany and Italy; but the home manufacturer had a good share of the world's trade, and, as regards the quality of English Quinine salts, an official investigation by the Italian Government some years ago showed them to be second to none.

The two alkaloids Cocaine and Theobromine were manufactured in this country, but relatively not on a large scale.

For the remaining alkaloids in the list we were undoubtedly dependent on enemy countries, as the very small quantities that may have been made here were almost negligible. They include Atropine, Eserine, and Homatropine, so very important in ophthalmic practice, as well as some alkaloids of less frequent use.

It is of interest to note that the alkaloid, Acetomorphine, was discovered by a Scotch chemist, and subsequently manufactured and put on the market by the Teuton, who, however, had to purchase English morphine for its production. While another, Cotarnine, was also put on the English market by a British firm long before the German product was boomed under a fancy name.

The Fourth group embraces about twenty chemicals known as *acids*.

Four, including lactic and tannic acids, were probably German; the remainder are English products, prepared in some instances from raw materials existing here, and in other instances from raw material imported from non-European countries, but the supply of which is largely controlled by British capital and enterprise, as in the case of Boric Acid. The raw material for Citric Acid is an Italian Government monopoly.

The Fifth group is composed of a large number of compounds of the common, and of the less familiar metals usually called salts.

It would be tedious to give any detailed account of the sources of these drugs. The group includes important remedies, as Calomel, Corrosive Sublimate, Nitrate of Silver, Bismuth Carbonate, Sulphate of Iron, Sodium Bicarbonate, Potassium Bromide and Iodide, and many others well known to all. It will suffice to state that we depend upon home production for the majority of these compounds. For many the raw material is found in England, for others, as bismuth, it is imported from America; for some, as mercury, from Spain; and for others, by no means the least important, from Germany. Reference will be made to this a little later.

The Sixth group embraces the simple compounds of Carbon, to the number of nearly twenty, sometimes known as "Organic Chemicals"—a name also applicable to the next group

which, however, possess a more complex composition.

The majority of the twenty simple compounds of Carbon are of great importance to the physician and surgeon. The group includes the general anæsthetics, Ether, Chloroform, and Ethyl chloride; the antiseptics, Carbolic Acid, Creosote and Iodoform, and also the well-known liquids alcohol and glycerine, so essential to pharmacy. Mere mention of the names of these substances is sufficient indication of their invaluable character. All of these were and, of course, are produced here in large quantities and of indisputable quality.

The other articles in this group are of much less importance. Three are of Teutonic origin, and the remainder English or American productions.

The Seventh group, comprising the complex compounds of Carbon, contains about forty drugs commonly known as the Synthetics.

The pre-war source of the great majority was, it must be confessed, Germany; very few of them were obtainable elsewhere, except possibly from Switzerland. France produced the very important substance adrenalin (synthetic), so largely used in surgical work, and also digitalin. An English house made Chlorbutol, and occasionally small quantities of two or three others; but for more than thirty out of the forty we were dependent on Central Europe.

The members of this group are not all of equal importance. One or two are dyes, used merely to give a distinctive colour to certain lotions, and one or two are substances whose medical value has not been fully established; but the majority comprises some very important drugs, such as Antipyrin, Chloral hydrate, Novocain, Phenacetin, Resorcin, Saccharin, Salicylic Acid, and its compounds Aspirin and Salol and Veronal, together with Salvarsan and Neo-Salvarsan

It is foolish either to minimise the importance of these drugs, or to detract from the work accomplished by the Teuton in their production, or to disguise our pre-war dependence on Germany for supplies. But, at the same time, we should not commit the mistake of supposing that synthetic drugs constitute the whole Materia Medica, for, as I have endeavoured to indicate, there are a large number of no less important drugs which were and are pre-eminently English products. It is, therefore, necessary to look at the matter of synthetic drugs in its proper perspective.

In these groups of drugs no reference has been made directly or indirectly to various preparations which bulk largely in the advertisement columns of the public press. For the most part they contain or are made up of quite ordinary substances, to which more or less fancy names have been given.

Two may be cited as illustrations—Lysol and Formamints. There is nothing mysterious about either of these articles except the names, and it may interest this audience to know that identical equivalents for both of these articles could be obtained of British manufacture for years before the war began; but, of course, they were not designated by the protected Teutonic names.

The London, in common with many other hospitals, used an antiseptic fluid identical in composition with and of equal value to Lysol at a cost, for the English article, of less than one-half that of the German.

Similarly, every pharmacy in the country sold English manufactured lozenges and tablets the equal of Formamints in all respects. Hence, it would appear that Lord Rhondda has brought his goods to the fair a day too late.

Having thus sketched lightly the position before the war, we can now pass to the consideration of—

II.—The Difficulties arising out of the War, and to what extent these have been surmounted.

With the outbreak of war there was also an outbreak of profiteering. Whether or not profiteering has been practised in other trades I do not know, but it is well known that in the drug trade certain firms—not, however, manufacturers, but dealers—threw any patriotism they may have had to the winds, and seized every opportunity of gaining control of the existing stocks, and also of the future output of home manufacturers, and then advanced prices entirely in their own interests, and thus made money out of the consumers' embarrassments, and were this a suitable occasion full details could be given. For instance, war had not been declared a fortnight before certain firms, warmly professing great consideration for their clients, assured them they had no desire to reap any advantage from the conditions created by the war; which desire they proceeded to manifest by practically repudiating their contracts and by raising, or attempting to raise, prices all round, even on drugs obtained from non-European countries.

Manufacturers, while making no promises,

loyally fulfilled their contracts, even though, in the case of one or two drugs, at a loss to themselves.

For a second instance we may take the case where the manufacturers' output of a certain drug had been secured for some months ahead by middlemen. These latter, taking advantage of the position created by themselves, advanced the price by 20 per cent. to 50 per cent., and, in one instance, a profit of many hundreds of pounds was made by a firm who neither saw nor handled the goods they sold.

This difficulty may be regarded as in some sense avoidable.

The real difficulties were comparatively few, but very formidable, and became intensified as the British blockade of Germany became more stringent. They were associated mainly with—

1. The supply of raw material, particularly of potash and of bromine.

2. The supply of synthetic and some other drugs.

A number of compounds of potassium are used in medicine, the raw material for which was obtained from Central Europe for the reason that Nature has endowed Germany with huge deposits of two potassium compounds—Kainite and Carnallite—which could be and were exported at such a price as to render all other sources of potashes unremunerative to work.

On the declaration of war inquiries were instituted to discover other sources of supply, and the Imperial Institute has published the results in a pamphlet entitled "The World's Supply of Potash."

Supplies may result from the revival of the kelp industry in Scotland and Ireland; but these are temporary, as the cost of production renders competition with the Stassfürt supplies impossible. Hopes are entertained that the discovery of large deposits of potash minerals in Spain may prove a serious competitor to the Germans in the future. It is, however, necessary to remember that the main difficulty lies chiefly in the direction of supplying potash for artificial manures, for the relatively small requirements of medicine and of the arts have been met without very great difficulty, but, of course, at a high price.

Prior to the war the world's supply of bromine was derived from the United States of America and from Germany, and the producers in these two countries had entered into arrangements whereby competition was largely eliminated, in consequence of which the Americans kept away from European markets.

The blockade left the Americans masters of the situation—a fact of which they were not slow to take advantage, for at one time the price of potassium bromide was 25*s.* per lb., as compared with 1*s.* 6½*d.* per lb. in July, 1914.

This serves to illustrate what we have had to pay for drugs for which England has had to depend during the war entirely on neutral countries, and it is instructive to set beside this enormous rise in price the moderate variations in respect of the prices of drugs the raw material for which is obtained within the Empire or is controlled by British enterprise and capital. Two instances will suffice for comparison. The production of Iodine from Chili saltpetre is largely controlled by Britain; hence the price of Potassium Iodide, which in July, 1914, was 12*s.* per lb., rose to 15*s.* per lb. only in December, 1915, and has since fallen to 12*s.* 2*d.* per lb., practically the pre-war price.

Similarly, the price of Morphine in July, 1914, was 9*s.* per ounce. On the outbreak of war with Turkey it rose to 13*s.* 6*d.* per oz., at which price it still remains. Had the control of Iodine and of Opium been in the hands of neutral nations the prices to which Potassium Iodide and Morphine would have risen baffle imagination.

Bromine, however, is now being prepared in France from sea water in large quantities, and at a price which enables it to compete with the American product.

These two problems of potash and of bromine, so essential in the treatment of nervous disorders, do not seem to have attracted public attention to the same extent as the question of synthetic drugs, to which we now turn.

A great deal of undeserved blame has been heaped on the heads of English firms manufacturing medicinal chemicals because they did not immediately undertake the production of these synthetic drugs, and the question has been frequently put, Why do not English firms commence the manufacture of these drugs and capture German trade?

Well, in the first place, the resources of British firms were taxed to the utmost in their endeavour to cope with the sudden and enormous demand for essentially British products for the needs of the Allied armies and of the civil populations; hence they had neither time nor staff to devote to fresh work.

The extent of these demands far exceeds the conception of all who are not directly associated with this work.

In the next place, it is to be remembered that you cannot raise armies of millions of men and have at the same time a surplus of labour to draw upon for new commercial enterprises, and

if you could it is not to be expected that plant and processes can be improvised in a day, which have occupied the enemy years of thought and labour in bringing to their present state of perfection.

Moreover, as has been pointed out by more than one distinguished scientist, it is one thing to make a trifling quantity of a drug in a laboratory, but quite another thing to produce the same article by the hundredweight and ton. The problem requires, not only the science of the chemist, but also the knowledge of the engineer to design the plant as well as the manual skill of the mechanic for its construction.

For these and other reasons very little was done in the early months of the war.

A start was, however, first made in the East End of London with the production of salicylic acid and its compounds, possibly because the raw materials are easily obtainable and because the process of manufacture is relatively simple, and in the early spring of 1915 the London Hospital received 1 cwt. of British-made sodium salicylate of excellent quality.

Aspirin was the next item to be tackled, and although the early attempts were not satisfactory, difficulties have now been surmounted, and more than one manufacturer is turning out tons of this article of the highest degree of purity.

Atropine sulphate, so essential in ophthalmic practice, and originally derived from Central Europe, is now being produced from Egyptian henbane in large quantities by at least two English firms.

It is unnecessary to weary you with detailed records of recent British achievements. It will suffice to mention a few of the "German" drugs now being produced in this country: Absolute Alcohol, Lanoline, Butyl chloral hydrate, Paraldehyde, Lactic acid, Homatropine, Phenacetin, Saccharin, Salol, Xeroform, Novocain, Salvarsan, and Potassium permanganate.

It is interesting to note that the chemical laboratories and staffs of various university colleges throughout the kingdom have been pressed into this work, and, as an illustration, I may mention that a certain drug supplied to the London Hospital bore a label, "Made in —— laboratory of —— University."

We now pass to the consideration of—

III.—The Period after the War.

This topic alone would suffice for the subject of a lengthy paper, and hence it is possible to indicate but one or two matters.

It will be generally admitted that the scientists of these islands are fully equal to the solution of all questions relating to synthetic drugs involving chemical knowledge both general and particular. And with the passing of the war there will also pass most of the difficulties with which manufacturers have at present to contend, particularly as regards provision of plant and of labour. Discussions of the turn of events after the war have centred, therefore, round what may be termed the commercial and financial aspects of the question.

It is assumed without doubt that the enemy countries will put forth the most strenuous efforts to regain the trade enjoyed by them before the war. Profiting by the lower rate of wages ruling in Germany as compared with those in this country, and aided probably by State subsidies, it is expected they will offer synthetic drugs at prices with which British manufacturers, if left entirely to their own resources, will be unable to compete.

If the production of synthetic drugs established here during the past two years is to survive the war, then some form of State aid seems to be necessary.

Difference of opinion exists as to the form which Government assistance should take. Firms which have had but limited experience of chemical manufacturing on a commercial scale ask for subsidies from Parliament. They desire to buy their experience and to build up a business at the expense of the State.

Firms, however, which are in possession of extended experience in the production of medicinal chemicals, having already tackled the new problem successfully, ask only for State assistance of a legislative character in order to ensure that the newer industries shall have a fair chance of surviving.

Some suggest that importation of synthetic drugs from enemy countries should be entirely prohibited for a period of years following the war; others suggest the imposition of a tariff which, while sufficiently high to give British firms a reasonable chance of competing with the German, should at the same time not be so excessive as to penalise the consumer.

Public bodies which are large consumers of drugs, such as the Voluntary Hospitals and the Municipal and other Infirmaries, can render much help in support of such legislative action by collectively agreeing to refuse to buy synthetic drugs emanating from Central Europe, even though such refusal may involve a slight extra cost to the ratepayer. Is British patriotism

strong enough to support such a step on the part of the governing bodies of these institutions?

The question of legislative assistance is by no means a simple one. For example, how is it proposed to deal with the competition of neutral countries? The United States is already a serious competitor to be reckoned with in the English market, and, in spite of high freights and insurance, the American can sell his goods in England at a lower price than the Englishman. In some cases the difference is not great; in others there is no comparison: thus some tons of American Phenacetin were recently sold in London at about one half the price of the English product.

Is then a tariff to be imposed on all non-British synthetic drugs, or only on the German article?

One writer suggests that money derived from a tariff ought to be devoted to research and education; but if a tariff is to be efficient in keeping out enemy products there will be no income from this source.

British manufacturers and scientists recognise that legislative protection does not by itself constitute a royal road to success.* Co-operation among themselves is highly desirable in arranging that too many firms are not engaged on turning out the same products; it has also been pointed out that by organisation and mutual concession the cost of manufacture can be reduced to a minimum if some firms undertake the production of essential intermediate substances for the use of other firms engaged in working up the ultimate synthetic drug.* Further, it is to be noted that certain intermediate products are required very largely in the dye industry, and upon the development of the latter to some extent depends the success of the synthetic drug industry.

There is a further question upon which there has been much agitation for many years, and concerning which there is also some difference of opinion. Endeavours have been made to persuade successive Governments to grant the use of duty-free alcohol on the grounds that the high duty handicaps the Englishman to such an extent as to make it impossible for him to think of competing with the foreigner who has the advantage of cheap alcohol.

The Government has made some concession in permitting the use of a spirit known as "industrial spirit," containing a smaller quantity of the denaturing constituents, but this does not give universal satisfaction. It may be the question will be investigated once again and further concessions granted.

Another complaint for which there is some justification, and which has occasionally been levelled by home manufacturers against the medical profession, is that new drugs of English manufacture put on the market under systematic names understood by all chemists are coldly received by the physician, but when these same drugs are made in Germany and introduced under a fancy name they are received with open arms. For example, Acetomorphine, already referred to, was first made and introduced in England by a Scotch firm, but little interest was manifested by the medical profession, whereas the same drug put on the market by the Germans, under the name "Heroin," was taken up with alacrity.

Furthermore, the partiality shown by some medical workers in the field of research for German reagents and solutions is difficult to understand, when it is remembered that British reagents of equal purity are easily obtainable.

One other criticism of our system of medical research is the lack of assistance sometimes accorded in physiologically testing newly discovered drugs of British origin.

It is pointed out that the organisation of the German chemical and medical worlds permits of the thorough investigation of the properties of any new remedial agent by experiments on animals, and also by employing it in clinical practice, if there be sufficient ground for expecting good results.

It is urged by some manufacturers that similar co-operation be established between British firms and workers in the field of medical research.

I have now brought to your notice a few points associated with a subject that has been much debated in the lay press, but I am afraid also a little misunderstood; possibly the discussion about to arise may lead to clearer views.

DISCUSSION.

The Chairman (Dr. Robert Hutchison, F.R.C.P.), in opening the discussion, said that, as a physician largely concerned in prescribing drugs, he had been cheered by the author's optimistic estimate of the situation. He had shown conclusively that this country was not so dependent upon enemy countries for important drugs as some people supposed, and that in the future it would be much less dependent upon them than it had been in the past. Except in a few cases there had not been any real difficulty since the war began in obtaining the absolutely necessary drugs, and he

* *See* Mr. Carr's paper, read before the Society of Chemical Industry, on these two points.

doubted if any patient had suffered in consequence of the war from want of a drug. The drugs whose absence had mostly been felt were the synthetic drugs, and the author had explained how it was that this country came to be so dependent on Germany for them. The reason why German synthetic remedies had been so largely taken up was partly because of their fancy names, to which reference had been made. Doctors were busy people and did not like to carry long names in their heads; it was so much easier to remember "Heroin" than "Acetomorphine." A great deal of the success of the Germans was due to getting really clever names for their drugs, and also to their assiduous advertising. Before the war scarcely a month passed but some German commercial traveller walked into a doctor's room with samples of some new remedy, and he had been told by the agent for a tonic food that the proprietors spent £70,000 in advertising the preparation in this country before it began to catch on. That showed to what an extent the Germans were prepared to go in pushing products in the English market. Again, as the author had pointed out, the people in this country had been handicapped to some extent by the want of that intimate co-operation between the scientific people and the manufacturers which existed in Germany, and also through not employing a proportionate amount of trained staff. The close association that existed between the manufacturers and the medical profession in Germany was also absent in this country, to the credit of the medical profession here. It was possible in Germany, by paying a sufficient sum, to get a professor of fair repute to write up in the medical journals any synthetic remedy or patent product produced in the German laboratories. He knew that was the case because he had received offers from German agents to write up their products in the *British Medical Journal* or the *Lancet* in order to get them boomed amongst the English medical profession. They could not understand why he refused those offers, many of which were extremely generous, nor the etiquette of the medical profession which made such things impossible here. Some of the synthetic remedies came on to the market backed by the *imprimatur* of a big name in the German scientific world, but if the real opinion of that German professor could be obtained it would not be very high, and he had simply been paid a large sum to say the best he could for it in print. Manufacturers had also been handicapped in this country from the want of cheap alcohol, and difficulty had arisen in connection with the so-called vivisection question. Rightly or wrongly, obstacles were placed in the way of animal experimentation in this country, even in testing drugs on animals before they were tried on human beings; and all those things, most of which were removable, had stood to some extent in the way of English manufacturers in the past. It was to be hoped that, after the war, the people of this country would make a point of being dependent on nobody but themselves for drugs absolutely essential for the treatment of disease, and maintain the sources of supply in their own hands.

MR. W. GEORGE WHIFFEN said the importance of the supply of the raw materials being under British control was strongly emphasised by what had taken place during the war. Bromine and potassium were of great importance in medicine and in agriculture, and yet—simply owing to the exorbitant demands by the American producers—potassium bromide, which, before the war, sold for 1*s.* 6½*d.*, had risen in price to 25*s.* per lb. Another source of supply was now available, bromine being manufactured in France from sea water, so that the enormous price realised by the Americans would never have to be paid again. Taking the other side of the case, and dealing with articles under British control, the price of strychnine in July 1914 was 1*s.* 7*d.* an ounce; and, in spite of the cost of freight and labour connected with the carriage from India of the nux vomica bean, which was the source of strychnine, the price had only risen to 3*s.* 4*d.* That was due to the fact that a good supply of the raw material had been ensured to the country by the Navy. Similarly, the price of quinine had nearly doubled, being 2*s.* 6*d.* at the present time as compared with 1*s.* 4*d.* before the war, in spite of the high cost of every chemical used in its manufacture, and that was another remarkable instance of the importance of the British control of raw materials. But for the fact that opium was grown within the Empire the price of morphia would probably have been sovereigns per ounce instead of 13*s.* 6*d.*, as it was at the present time. Since the outbreak of war with Turkey the price of opium had not changed. There was no doubt that the group of synthetic drugs which included phenacetin, the salicylates and, salol, was manufactured at the present time to more advantage in America than in this country, owing to the fact that they were not hampered by want of labour and raw materials; in fact, the basis of them, phenol, could only be obtained in this country by permission of the War Office. Since the outbreak of war there had been a very considerable exodus of technical skill of doubtful nationality from Germany to America, and the Americans had properly made good use of it. It therefore did not surprise him to hear that phenacetin of excellent quality could be obtained from the States at a lower price than that at which it could be produced in England at the present time. He had no doubt, however, that in course of time the British would be able to compete with the States in that respect, owing to the high cost of labour and machinery in America in consequence of high tariff duties. There was no better example of the importance of the Empire having control of raw materials than in connection with iodine and the important compounds made from it, such as iodide of potassium, iodide of sodium, and iodoform, which were actually cheaper at the

present time than in June, 1914. All those articles except potassium were under British control, and, in spite of the fact that potassium was worth ten times now what it was in 1914, iodine was cheaper to-day than it was in 1914.

MR. J. C. SHENSTONE thought that, from the commercial point of view, it was the pharmacist's duty to carry out the doctor's orders, and that it was not his place to criticise them. It must be remembered that, although the London Hospital included on its staff a number of eminent medical men, there were many other hospitals in which, although the practice was very similar, a variation in the drugs prescribed was noticeable. It was therefore desirable to consider the question from a wider basis than that of the London Hospital practice. If the author desired to ascertain what all the medical men in the country felt, it would have been better for him to base his remarks on the Codex published by the Pharmaceutical Society, which was the basis of prescriptions received by chemists in every part of the world. He agreed that for purely commercial reasons it was desirable that the drug business should not after the war slip back entirely into the hands of the Germans. He had noticed that the author had not referred to taraxacum, dandelion juice, a very old-fashioned drug, the demand for which was increasing rather than diminishing. He happened to know that at the present time fifty tons of dandelion juice were badly wanted but could not be obtained.

MR. J. E. LANGFORD MOORE thought the optimistic tone of the paper was distinctly encouraging. He crossed swords with the last speaker in reference to the necessity of taking a wider range of the subject than that dealt with by the author, who had had a considerable experience of drugs. His own twenty-five years' hospital experience led him to believe there was a distinct diminution in the variety of drugs used, and that would continue in the future, because it was obvious, as education advanced and physiological problems were cleared up, that reliance would be placed a good deal more on particular drugs than had been the case in the past. The unfortunate experience the country had been through since the war had taught the lesson that there were a great many drugs that it was possible to do without very well, and he saw no reason why they should ever return. The author had omitted one side of the problem connected with the future which it appeared to him needed careful watching, namely, that our greatest competitors in regard to drugs would not be the enemy States in Central Europe, but the countries of the East, such as Japan and China. That was very apparent in view of what was happening with regard to Indian trade, but the difficulty might be set right in the future when the tariff question came up for consideration.

MR. F. RANSOM thought that those who attempted to grow certain herbs on a large scale in this country might be doomed to disappointment, and he therefore desired to utter a word of warning on that question. Although belladonna at present fetched ten times the price it did before the war, it was very undesirable that more belladonna should be produced than the world required. The same remark also applied to henbane, and it was a question whether the species obtained from Russia was exactly the same as that cultivated in this country. If Egyptian henbane eventually superseded all solanaceous plants it was unnecessary to consider the future of belladonna or henbane, because there was an inexhaustible supply of Egyptian henbane. There was enough digitalis in the country to supply the whole world, but the difficulty was to get it collected. Before the war, good dry digitalis from Europe was sold at 25*s.* to 30*s.* a hundredweight, which was not sufficient to pay for the cost of collection in this country. If it could be collected more cheaply plenty of the plant was available. Gentian, which the author had stated came entirely from Central Europe, was now imported from Spain in considerable quantities, and there was no reason why England should not continue to obtain it from there. Styrax, which was now almost unobtainable, came almost entirely from the Turkish Empire, and he did not think the country would suffer much if it never imported any of it again.

LIEUT.-COLONEL ALLAN J. C. CUNNINGHAM mentioned that *datura stramonium*, which the author had not referred to, was used in many preparations for the relief of asthma; it could be obtained in large quantities in India, and was well known to the professional poisoners there. The Chairman had stated that he thought the people of the country had not suffered much from the want of drugs through the war; but a friend of his, who suffered from a serious affection of the mouth, for which he had been prescribed a glycerine wash by his doctor, could not obtain it from the chemist, owing to the fact that the Government had recently commandeered all glycerine.

MR. OSWALD E. BENNETT said he had been much interested in the point raised whether the control of crude material necessarily implied an advantage to this country. He believed that the control of the sources of iodine was the main reason why the potassium iodide was so much higher in price than bromide, and if it were not for that control it might have been sold at a much lower figure. It was well to remember that unless the country could be sure of the patriotism of the individuals who controlled the supplies, it did not follow that the people would be advantaged by control rather than by freer competition.

MR. J. C. PHILIP said that he had been working in connection with the Royal Society Committee which organised the production of drugs in the colleges and universities, and desired to emphasise the fact that the necessity for their production

in those places had now been removed, owing to the enterprise of manufacturing firms. Although in the early days of the war commercial firms were not in a position to undertake the production of synthetic drugs, the situation had been revolutionised in the last twelve months. He was surprised to hear the author say that potassium permanganate was being made in the country at the present time. The information he possessed was that it was sodium permanganate. He was informed that the total quantity of potassium permanganate in the country did not exceed three tons, but that there were large quantities of sodium permanganate. Reference had been made by the author to the fact that in the past British medical men had depended to a large extent for their reagents on German sources, but he confessed that his experience of English firms in pre-war days was not altogether fortunate. On one occasion when he required pure sodium chloride he found it contained manganese.

Mr. F. A. Hocking, in reply, said he did not think Mr. Shenstone had told the whole of the story in connection with the fifty tons of taraxacum that he had said was required. He happened to know that it was not wanted for home consumption at all, but for export to some patent medicine vendors in the States; and he told his informant, who was a partner in one of the big firms of medicinal plant growers, that he would do his best to prevent him getting the fifty tons. He had mentioned that he had taken the London Hospital data as the basis of his paper because it was representative. By that he meant it was not by any means unique, and that the experience was typical of other hospitals. The Codex was a useful book of reference, but there were some things mentioned in it which it was quite impossible to obtain in peace times in this country. There were other books very much more useful. He did not think Mr. Shenstone had made the difference he should between what could be sold and what need be sold. Personally he had concerned himself in the paper with what need be produced, and not with what could be produced in order to find a market. It seemed to him waste of effort and capital in war time to engage in the production of herbs of very doubtful utility. *Datura stramonium*, to which Colonel Cunningham had referred, was used at the London Hospital as a constituent of asthma powder, and he believed it was derived from Europe. It was interesting to know that unlimited supplies could be obtained within the British Empire. The statements that had been made in regard to iodine had reference to a monopoly which existed in peace time. The point he raised was that, monopoly or no monopoly, the fact that British capital controlled the production of iodine had prevented the price of iodine compounds rising so enormously as had been the case with material the control of which was in neutral countries. He believed he was correct in saying that potassium permanganate was being produced, but he was afraid it would be impossible to buy it on the market at the present moment. He also knew that sodium permanganate was being produced, as he had seen the process in actual operation.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Hocking for his paper, and the meeting terminated.

CORRESPONDENCE.

THE BEN-I-ISRAEL.

In reply to Mr. Hylton B. Dale's letter in the *Journal* of February 23rd, I wish to say that Armenia, with Georgia—the Russian form of the Persian *Gurdschistan*, "the Brave-men's land"—roughly comprises the whole of the uplands extended between the Caucasus Mountains and the headwaters of the Euphrates, and between Persia and Asia Minor, and lies, therefore, in the direct line of the southern route of the prehistoric migrations of the Aryan race from some vague place in Central Asia—about the present Desert of Gobi—into Europe, and of every historical conqueror of Anterior Asia from the west, and of Europe from the east.

The name Armenia, for this country, is first found in the cuneiform inscriptions of Darius Hystaspes—"*Armaniya*"—B.C. 486–561; but was probably first used by the Aryan Lydians after the fall of Nineveh in the seventh century B.C. For Sayce has clearly shown, in his "Vanic Inscriptions," that before that date the people of the country were Hittites, who called themselves Viania, or Biania, a name which possibly survives in that of Lake Van. The Assyrian name of the country was *Urartu* [the Hebrew Ararat], meaning, as is thought, "the Mountain of the Moon-Goddess"; and the Lydian word Armenia is said to be a translation of Urartu, in some such original form as *Hara-Meen* or *Hara-Mynas*.

After the Assyrians, Armenia was successively ruled by the Persians, Greeks [Seleucidæ and Arsacidæ], Parthians, and Romans, and again by the Byzantine Greeks and Saracens; and then, from A.D. 859 to 1045, by *the noble Jewish* dynasty of the Bagratides. In the thirteenth to fourteenth century it was subjugated by the Turks, and is now divided between the Turks, Persians, and Russians.

The people of a country so situated, and with so terrible a history, though they may be of one language and one religion, must necessarily be of very mixed race; and, as everywhere, the features and general physique of a man are the surest indications of his race, no one who has known the Armenians in India, and Persia,

and Egypt, and here in England, can have any doubt of their being partly of Hebrew descent. The very Ben-i-Israel themselves, as I have seen them myself low down the Euphrates, and in India, frequently present aquiline noses, betraying the admixture of Aryan with Semitic blood; and I have invariably found that any Muslim, Nestorian, or Armenian with a vulturine nose, was an "Israelite indeed," notwithstanding the beguilements of his Gentile religion.

GEORGE BIRDWOOD.

OBITUARY.

WILLIAM HENRY HUNTER, M.Inst.C.E.—Mr. William Henry Hunter, who had been a member of the Royal Society of Arts since 1899, died at Woodley, Cheshire, on February 27th.

He was born in 1849, and educated at the College of Physical Science, Newcastle-upon-Tyne. In 1872 he was appointed resident engineer on the Hylton and Monkwearmouth Railway, and in the following year he was engaged on the reconstruction works of the River Weaver Navigation. This post he held for about nine years, after which he began his connection with the Manchester Ship Canal. He became chief assistant engineer on the design and construction of the canal in 1887; in 1895 he was appointed chief engineer, and on his resignation from this post, after fifteen years' service, he became consulting engineer.

In 1905 Mr. Hunter represented Great Britain on the Board of Consulting Engineers appointed by the President of the United States to consider the plans for the construction of the Panama Canal.

GENERAL NOTES.

DEAFENED SOLDIERS AND SAILORS.—The annual report of the National Bureau for Promoting the General Welfare of the Deaf shows that, amongst its many other activities, the Bureau has not overlooked the case of soldiers and sailors deafened by gun-fire or by shell-shock. Through its instrumentality a number of men have received special treatment at London hospitals. The London County Council is about to establish lip-reading classes for soldiers; and the War Pensions Committee is being urged to make a maintenance grant to such cases, in order to enable them to continue their training in lip-reading. In certain quarters there has been a tendency to belittle the value of lip-reading; but, in the opinion of those best qualified to judge, there is no doubt that this is by far the most satisfactory method of enabling men who have lost their hearing to regain touch with their fellows.

UNIVERSITY OF LONDON WAR LIST.—The Vice-Chancellor of the University of London will be glad to receive the following information with regard to members of the University who have served or are serving in His Majesty's Forces: Name (Christian names in full); College and University career; rank and regiment or other unit; particulars of service (including war distinctions, and whether wounded, retired, or fallen); with dates. Address replies to—University of London War List, South Kensington, London, S.W.

VICTORIA AND ALBERT MUSEUM.—The war having temporarily claimed the London residences of the Duke of Buccleuch, the Duke of Devonshire, and the Duke of Westminster, the valuable collections of furniture which they contained have been deposited by their owners on loan in the Victoria and Albert Museum. The principal collection is that lent by the Duke of Buccleuch from Montagu House. It consists, for the most part, of French furniture belonging to the period of Louis XIV. to XVI., and includes a remarkable series of Boule examples; pieces signed by Carlin and Joseph; chairs and screens covered with Beauvais and Gobelins tapestry; and many other valuable specimens. The collection lent by the Duke of Devonshire from Devonshire House consists almost entirely of furniture designed by William Kent, the architect of that house when it was rebuilt in 1734, after a fire in the preceding year. It includes about twenty typical examples of Kent's work, and thus will afford to students a unique opportunity of studying the characteristic style of this important artist. Among the pieces lent by the Duke of Westminster from Grosvenor House, the most striking are a pair of Boule *armoires*, similar to the well-known examples in the Wallace Collection and at Windsor Castle.

THE INSTITUTE OF METALS.—The annual general meeting of the Institute of Metals will be held in the rooms of the Chemical Society, Burlington House, Piccadilly, W., on Wednesday, March 21st, and Thursday, March 22nd, 1917. The following communications will be submitted: (1) "The General Properties of Stampings and Chill Castings in Brass of Approximately 60/40 Composition," by Owen W. Ellis, B.Sc. (London); (2) "Machining Properties of Brass," by Owen W. Ellis, B.Sc. (London); (3) "Surface Tension and Cohesion in Metals and Alloys," by Sydney W. Smith, B.Sc., A.R.S.M. (London); (4) "Aluminium Production by Electrolysis: A Note on the Mechanism of the Reaction," by R. Seligman, Ph.Nat.D. (London); (5) "Annealing of Nickel Silver (Part II.)," by F. C. Thompson, D.Met., B.Sc. (Sheffield); (6) "Metal Melting as Practised at the Royal Mint," by W. J. Hocking (London); (7) "Coal Gas as

a Fuel for the Melting of Non-ferrous Alloys," by G. B. Brook (Sheffield); (8) "High Pressure Gas Melting," by C. M. Walter, M.Sc. (Birmingham); (9) "Contribution to Metal Melting Discussion," by H. M. Thornton (London) and H. Hartley, M.Sc. (London); (10) "An Electric Resistance Furnace for Melting in Crucibles," by H. C. Greenwood, D.Sc. (London), and R. S. Hutton, D.Sc. (Sheffield); (11) "Ideals and Limitations in the Melting of Non-ferrous Metals," by Carl Hering (Pa., U.S.A.); (12) "Metal Melting in a Simple Crude Oil Furnace," by H. S. Primrose (Ipswich).

ASBESTOS IN QUEBEC.—The asbestos deposits of Quebec are the most important yet discovered, and are said to supply 80 per cent. of the world's consumption. The principal deposits are at Thetford, Black Lake, Robertsonville, Dunville, and East Broughton, in the counties of Megantic and Richmond. Large mills are in operation preparing the asbestos for the market. The annual production is over 160,000 tons, valued at about $3,850,000, according to the last report of the Mines Branch of the Dominion Department of Mines, and includes a wide variety of grades from the long-fibred crude asbestos, valued at about $400 per ton, down to the shortest mill fibre, valued at only two or three dollars per ton, and asbestic, used for wall plaster, and valued at from 75 cents to $1.50 per ton.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 7.—JAMES HARRIS VICKERY, LL.B., "German Business Methods." The RIGHT HON. SIR GEORGE HOUSTON REID, G.C.B., G.C.M.G., K.C., M.P., will preside.

MARCH 14.—DR. J. AUGUSTUS VOELCKER, "Fertilisers and their Supply in War Time." A. D. HALL, F.R.S., Chairman of the Development Commission and late Director of the Rothamsted Experimental Station, will preside.

MARCH 21.—G. W. JONES, "Colour Printing, and some Recent Developments." CARMICHAEL THOMAS, Chairman of the *Graphic* and *Daily Graphic*, will preside.

APRIL 18. — HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

APRIL 25.—SIR FRANCIS FOX, M.Inst.C.E., "Flour and Bread." CAPTAIN CHARLES BATHURST, M.P., Parliamentary Secretary, Ministry of Food, will preside.

MAY 2.—J. C. SHENSTONE, F.L.S., M.P.S., "Herb-growing in the British Empire: its Past, Present, and Future."

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

APRIL 19.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

Dates to be announced later:—

D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

MARCH 6. — MONSIEUR M. HORN, LL.D. (Brussels), "The Economic Development of the Belgian Congo." A. D. STEEL-MAITLAND, M.P., Parliamentary Secretary, Colonial Office, will preside.

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

PROFESSOR WILLIAM RIPPER, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency."

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m.:—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

Syllabus.

LECTURE I.—MARCH 5.—The spirit of memorial design—Art sacrifice and utility—The matter of inscriptions—Development of various monumental types and conventions—Praying figures—Canopied monuments—Mural tablets—The placing of monuments in buildings—Historical sketch.

LECTURE II.—MARCH 12.—The designing of modern monuments—Architect and sculptor—Influence of setting—Adoption of historical styles—Choice and treatment of materials—Brass, stone,

marble, wood, lead—Lettering—Heraldry—Emblems and symbols—Christian feeling in memorial art—Crosses and Calvaries—The churchyard.

LECTURE III.—MARCH 19.—Equestrian figures —Group memorials—Public school, regimental and civic monuments—The War memorial—Teuton *versus* Latin spirit in design—The Christ of the Andes — Columns and arches — Buildings and bridges—Monumental art and town planning.

HOWARD LECTURES.

Monday afternoons, at 4 p.m.:—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies: (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market." Two Lectures.

April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Aldred Lecture.) Mr. L. Weaver, "Memorials and Monuments." (Lecture I.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Mr. A. W. C. Shelf, "High Tensile Steel *versus* Mild Steel for Reinforced Concrete."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Mr. W. A. Tookey, "The Composition of Power Gases."

Geographical Society, Burlington-gardens, W., 5.30 p.m. Colonel Sir Francis Younghusband, "Indian Frontier Geography."

TUESDAY, MARCH 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Dr. M. Horn, "The Economic Development of the Belgian Congo."

Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Mr. R. Unwin, "Germany: Her Civic Strength and National Weakness."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. E. Dalby, "Internal Combustion Engines." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Arts, Royal Academy of, Piccadilly, W., 3.30 p.m. Sir Frank Short, "Mezzotint."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. J. L. Hodgson, "The Commercial Metering of Air, Gas, and Steam."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. F. C. Reynolds, "Some Simple Experiments with Polarised Light."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. R. I. Pocock, "Exhibition of the work of the Beavers in the Society's Gardens." 2. Dr. F. E. Beddard, "On the Scolex in the Cestode Genus *Duthiersia*, and on the Species of that Genus." 3. Captain S. R. Douglas, "An Experimental Investigation of the Migration of Woodcock Breeding in the West of Ireland."

Faraday Society, at the Chemical Society, Burlington House, W., 8 p.m. Discussion on "The Training and Work of the Chemical Engineer," to be opened by Sir George Beilby. Papers by: 1. Professor F. G. Donnan, "The Training of the Chemical Student for Work in the Factory." 2. Mr. C. R. Darling, "The Training of the Works Chemist in Physics." 3. Mr. W. R. Cooper, "A Plea for the Forgotten Factor in Chemical Training."

WEDNESDAY, MARCH 7... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. J. H. Vickery, "German Business Methods."

Aëronautical Society of Great Britain, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor F. G. Hopkins, "The Selection and Preparation of Foods in War Time."

Oriental Studies, School of, London Institution, Finsbury circus, E.C., 5 p.m. Mr. A. Yusuf Ali, "The Importance of Hindustani."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MARCH 10...Royal Institution, Albemarle-street, W., 3 p.m. Dr. C. W. Saleeby, "Imperial Eugenics—Saving the Soldier." (Lecture I.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 2, 1917.

Journal of the Royal Society of Arts.

No. 3,355. VOL. LXV.

FRIDAY, MARCH 9, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 12th, at 4.30 p.m. (Aldred Lecture.) LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." (Lecture II.)

WEDNESDAY, MARCH 14th, at 4.30 p.m. (Ordinary Meeting.) DR. J. AUGUSTUS VOELCKER, "Fertilisers and their Supply in War Time." A. D. HALL, F.R.S., Member of the Development Commission, and late Director of the Rothamsted Experimental Station, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

ALDRED LECTURE.

On Monday afternoon, March 5th, Mr. LAWRENCE WEAVER, F.S.A., delivered the first lecture of his course on "Memorials and Monuments."

The lectures will be published in the *Journal* during the Summer recess.

COLONIAL SECTION.

Tuesday afternoon, March 6th, 4.30 p.m.; Mr. A. D. STEEL-MAITLAND, M.P., Parliamentary Secretary, Colonial Office, in the chair. A paper on "The Economic Development of the Belgian Congo" was read by MONSIEUR M. HORN, LL.D. (Brussels).

The paper and discussion will be published in a subsequent number of the *Journal*, though, in consequence of the restriction of paper supplies, there will be some unavoidable delay before they can appear.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1917 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 24th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

1864, Sir Rowland Hill, K.C.B., F.R.S.
1865, His Imperial Majesty, Napoleon III.
1866, Michael Faraday, D.C.L., F.R.S.
1867, Sir W. Fothergill Cooke and Sir Charles Wheatstone, F.R.S.
1868, Sir Joseph Whitworth, LL.D., F.R.S.
1869, Baron Justus von Liebig.
1870, Vicomte Ferdinand de Lesseps, Hon. G.C.S.I.
1871, Sir Henry Cole, K.C.B.
1872, Sir Henry Bessemer, F.R.S.
1873, Michel Eugène Chevreul.
1874, Sir C. W. Siemens, D.C.L., F.R.S.
1875, Michel Chevalier.
1876, Sir George B. Airy, K.C.B., F.R.S.
1877, Jean Baptiste Dumas.
1878, Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.
1879, Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.
1880, James Prescott Joule, LL.D., D.C.L., F.R.S.
1881, Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.
1882, Louis Pasteur.
1883, Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.
1884, Captain James Buchanan Eads.
1885, Sir Henry Doulton.
1886, Samuel Cunliffe Lister (afterwards Lord Masham).
1887, HER MAJESTY QUEEN VICTORIA.
1888, Professor Hermann Louis Helmholtz.
1889, John Percy, LL.D., F.R.S.
1890, Sir William Henry Perkin, F.R.S.
1891, Sir Frederick Abel, Bt., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.
1892, Thomas Alva Edison.
1893, Sir John Bennet Lawes, Bt., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.
1894, Sir Joseph (afterwards Lord) Lister, F.R.S.
1895, Sir Isaac Lowthian Bell, Bt., F.R.S.
1896, Professor David Edward Hughes, F.R.S.

1897, George James Symons, F.R.S.
1898, Professor Robert Wilhelm Bunsen, M.D.
1899, Sir William Crookes, O.M., F.R.S.
1900, Henry Wilde, F.R.S.
1901, His Majesty King Edward VII.
1902, Professor Alexander Graham Bell.
1903, Sir Charles Augustus Hartley, K.C.M.G.
1904, Walter Crane.
1905, Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.
1906, Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.
1907, The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.
1908, Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.
1909, Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.
1910, Madame Curie.
1911, The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
1912, The Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.
1913, His Majesty King George V.
1914, Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.
1915, Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.
1916, Professor Elias Metchnikoff.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, February 15th, 1917; the Right Hon. Lord Islington, P.C., G.C.M.G., D.S.O., Under-Secretary of State for India, in the chair.

The paper read was—

THE INDIAN SILK INDUSTRY.

By Professor H. Maxwell-Lefroy, M.A., F.E.S., F.Z.S.,

Imperial College of Science and Technology, South Kensington.

In the time available to-day it is not possible to deal with an industry so large, so scattered, so varied, as the silk industry in India. In the report prepared by Mr. Ansorge and myself the full details of the industry are recorded, and this report will shortly be available. This afternoon I propose to describe very briefly the general conditions of the industry, to state its extent, and to enable you to see whether India can ever be a large source of supply of silk raw products to this country.

There are in India four kinds of silkworm: that feeding on mulberry, which is the usual silk of commerce; the tasar and muga, wild silks which resemble shantung; and the unique eri, the domesticated castor-feeding silk. Of the mulberry there are two descriptions, the single-brooded race, grown in Kashmir and the Punjab, from French and Italian seed; the many brooded races of Bengal, Mysore, Assam, Burma. Both are reelable and yield two products, raw silk and waste silk; but the quality of the products of the French cocoon is far superior to that of Bengal and Mysore cocoons, and their uses in trade are quite distinct. So are the conditions of their production: the largest industry is concerned with the production of the many-brooded races in Mysore and Bengal; the worms are reared in the people's houses, fed with leaf plucked from the fields; the cocoons are spun on trays and are killed by the sun's heat; the reeling is done on a primitive apparatus over a fire, usually two threads at a time, and yielding an uneven coarse thread, little appreciated outside India. In Mysore the silk produced is woven locally, or in the Madras weaving centres; of the Bengal silk much is used in Bengal, Nagpur, Amritsar, etc., but much is exported, chiefly the product of the filatures of which a few remain, still under the control of a European firm. The Assam and Burma silk is locally used in weaving; it is not a large amount, and is grown wholly for home consumption. This silk is from worms fed entirely on mulberry grown as a field crop as bushes. The superior French race, grown in Kashmir and the Punjab is fed on the leaves of tree-mulberry, and the industry owes its existence to the fact that, in Kashmir, mulberry grows wild all over the valley. There, too, the people grow the worms in their houses; but the cocoons they deliver to the State, and the reeling is wholly done at a central filature. In the Punjab the little silk produced is sold for reeling at Amritsar or sent to Bengal for reeling.

The extent of the mulberry industry can be best shown by figures. These are approximate but not wildly exaggerated (see p. 291).

The silk products are disposed of thus: Mysore, raw silk, one-third to Madras, two-thirds locally woven; waste silk exported to Europe. Madras, raw silk used in Madras, waste silk exported. Bengal, raw silk woven locally and in Bombay cities, Nagpur, Benares, Amritsar, etc. Filature silk exported to France; waste silk spun locally by hand or exported to Europe. Assam and Burma all used locally. Kashmir, nearly all exported to France. Punjab, locally reeled or sold as cocoons for reeling in India.

		Green Cocoons.	Raw Silk.	Rearers.
Mysore	32,000 acres	15,360,000 lb.	1,152,000 lb.	70,000
Madras	12,000 ,,	5,000,000 ,,	400,000 ,,	25,000
Bengal	19,000 ,,	8,000,000 ,,	600,000 ,,	43,000
Assam	Trees	——	12,000 ,,	4,000 families.
Burma	,,	——	15,000 ,,	1,500 ,,
Kashmir	,,	2,640,000 ,,	96,000 ,,	80,000
Punjab	,,	12,000 ,,	1,800 ,,	800

Tasar is wholly a wild insect, which inhabits a great part of the hilly, jungly areas, centring in the great Chota Nagpur and Orissa Forests. In this area it is abundant enough to be worth collecting, and there are classes of people, of hill tribes, who add to their earnings by putting worms out on trees and guarding them. The production is an ancient industry, formerly supplying local needs, furnishing an article for barter with cultivating villages near jungle tracts, who used the silk. And it is an industry that has altered much as the forest areas have been controlled and exploited. As the country opens up the industry naturally declines; the cattle-herds who collect the cocoons, the tribes who rear them, find cultivation or field labour safer and more profitable. The production of tasar is connected with restrictions in food, tobacco and other enjoyments, which are irksome. Disease in the worms is uncontrollable and often disastrous.

So the tasar-producing industry lessens, and will decline unless science can be applied, can combat disease, can make the crop sure and a large one. There are peculiar difficulties, both scientific and other, in this question, and it is not certain that there is justification for the cost of tackling them.

There are no figures of the production of tasar. Wild estimates are possible, and I give you mine, with the proviso that they may be quite double or treble the real figures :—

Muga is a similar insect, feeding on other plants than mulberry, and found only in Assam; it is grown similarly and used similarly. There is little use for it outside Assam, and the bulk is locally used. I can give an estimate of production, partly from the admirable work of Rai Bahadur B. C. Basu :—

Production: 225,000 kahans of 1,280 cocoons each, value Rs. 6,25,000 (£41,500); thread export: 542 maunds of 82 lb., value Rs. 2,16,800 (£13,300); total production: thread, 1,750 maunds; spun thread, 3,000 maunds. Engaged, 15,000 families rearing; 10,000 persons weaving, etc. Total value of exported thread and cloth made, Rs. 14,03,000 (£100,000). Both tasar and muga are peculiar silks, locally reeled by simple processes, and little adapted to export. A French firm for many years reeled tasar and exported it; but they have closed their business. There is a small use of tasar in Cawnpore for making braid for puttees, otherwise tasar and muga are reeled and worn locally, and the waste spun by hand for home weaving.

Lastly, the eri silk cocoon is derived from a domesticated insect, grown in many villages in Assam for local sale and use. The worms feed on castor, the cocoon is unreelable, but is spun by hand for home weaving. Just as in former times flax was spun and woven in Europe, so now, in many houses in Assam, the girls tend the worms, spin the cocoons and weave the cloth for wear, for sale, or for the

	Rearers.	Twisters.	Weavers.	Total.
Chota Nagpur	65,000	20,000	50,000	148,000
C.P.	6,000			
Bengal	5,000			
U.P.	2,000			

250,000 kahans of cocoons (1,280 = 1 kahan).
Value Rs. 1,750,000 = £120,000.

trousseau. There is a surplus, produced mainly by the tribes in the hills, which comes down in barter for cloth, for salt, for rice, and which reaches Gauhati and is sold for export. It is sent to the Continent and is spun, mixed with other silks, wool or other fibres.

The Assam figures of Rai Bahadur B. C. Basu are :—

Cocoons produced	5,325 maunds	
„ exported	1,000 „	Value Rs. 1,08,000 (£7,000).
„ spun	4,325 „	
Thread made	3,150 „	
„ imported	150 „	
„ exported	1,026 „	Value Rs. 2,09,000 (£13,500).
„ woven	2,234 „	
Cloth made		Value Rs. 10,72,000 (£67,000).
		Total Value . . . Rs. 13,89,000 (£86,400).

People engaged probably } 15,000 families in rearing,
5,000 „ in spinning and weaving.

Some years ago the question of eri growing outside Assam was taken up. The industry was started in many parts of India. A mill in Bombay bought cocoons and spun them into yarn, which is still used in Benares and Bhagalpur; but the effort has failed, and eri is now practically confined to Assam as before.

With the many lantern slides which illustrate the production of cocoons and silk, and with the above condensed descriptive matter, you can get some idea of this industry. It is largely a subsidiary industry to cultivation; it is a cottage industry, yielding from ten to three hundred rupees a year to the family who practise it; it engages as rearers and reelers some 400,000 people; it is limited to very definite areas, some of which are decreasing in extent. There are in India some 300 million people, chiefly cultivators; of these one in a thousand adds to his earnings by growing mulberry or castor for feeding silkworms—why do not more do it?

There are definite factors which affect this. They are—climate, custom, prices, disease, ignorance. As regards climate, silkworms, to be profitably grown, must have the right climate; and this climate must persist long enough to feed a brood of worms, say, for two months at a time. In Kashmir they get one crop in May-June; before that it is too cold, after that there is no leaf, and later it gets too cold. In the Punjab there is one crop in February-March; before that it is too cold, after that it is too hot. In Bengal the best crops are in October-November, February-March; at other times it is too cold, too hot, or too moist. So for all India one can determine exactly when conditions are right or wrong, and areas where silk is produced are those where conditions are right.

Secondly, custom—by that I mean the practices of the people, dictated by religion. Many classes will not do silkworm-growing as it entails killing the chrysalides. In Assam and Burma those who do it are generally looked down upon; in the United Provinces, for instance, the largely-predominant Hindu population would not do it. In Travancore, the lower castes and Christians may take to it, but no one else will. Those of you who know India will understand; those who do not must try to realise it. Just as you cannot produce an unlimited amount of long-staple cotton in India because of the insect pests, so you cannot grow unlimited silk because of custom. People in England find it difficult to realise this.

The third factor is price. The silk production of Bengal is probably now less than a tenth of what it was forty years ago, because the prices of rice and jute have gone up steadily, and the price of silk has remained steady or fallen. A pound of silk was equal to 120 seers (220 lb.) of rice thirty years ago, but is only equal to forty now. And as the rearer eats rice he has, wherever possible, abandoned silk: he is better off, and we need not regret him.

Fourthly, there is in all silkworms a disease called pebrine and others called flacherie, grasserie, etc. The first appeared about 1875 in India, and has done great harm; we have treated it on European methods which we now find do not apply in India. Much money has been wasted in Bengal with no effect, and we have now to tackle it properly or see the industry decline.

Lastly, ignorance. There are many places in India where silkworms will grow, but no one knows when or how; but they try, fail and give it up. Many native States have tried and failed; and it is probably only now that we

realise exactly what must first be learnt before we can start growing silkworms in a new area. When we have skilled people who can say exactly when and how silkworms can be grown, then silk will be grown in new areas suited to it.

If you read the detailed report you will understand better; you will better realise the immense difficulties ahead if India's resources in silk are to be developed, and you will understand why the recommendations are what they are. I cannot now discuss these; they are before the Indian Government, and it is not my business to-night to discuss them; but I hope you have a fairly clear picture of what the industry is.

We will now turn to the fascinating aspect of the working up of the silk. It is useless giving word pictures, so I shall rely on slides made from photographs taken in all parts of India last year. First, the raw silk is taken as it is bought in skeins and is opened out; it is then placed over a swift or over two bamboos or three upright rods, and is wound off on to bamboo reels; as the thread passes through the fingers its thickness is estimated and it is sorted into four qualities—the finest goes to one reel, the medium to another, the coarse to a third, the very coarse is rejected. Each quality has its uses, and for this reason the Indian likes and buys coarse Indian or China silk, because in the one skein he gets the qualities he needs for weft and for warp.

Each quality is then tested for its proper use: the warp is usually twisted, first each thread singly, then two together for the best warp. I illustrate a variety of methods by which this is done; they vary in mechanical perfection from the very slow crude single-thread process to the machine doing forty threads at a time. This work is all done by special workers, men or women, in the weavers' quarters or the village.

After twisting comes degumming, dyeing, rewinding and warping. All are done in the houses with simple devices; the warping may be done in the open, on upright sticks, or over pegs on a board, or on a revolving mill from a creel of bobbins. There are all degrees of method. The warp is then laid out, brushed and the healds knitted on by a special worker. In some cases they use eyed healds and the thread is drawn in. The thread is then drawn through the reed, and fixed to the beam of the loom.

Looms vary greatly in type, and there is in India an enormous variety of method, from the simple loom with two shafts to the exceedingly complex *kamkhwáb* loom, weaving elaborate brocades.

The object of the weaver is to secure variety of texture and pattern; he can do this by five methods—actual weaving, *i.e.* methods of so arranging the warp threads that he can produce a texture or pattern; arrangement of differently coloured warp and weft threads, so that he gets a pattern; arrangement of variegated warp or weft threads dyed in sections, giving pattern; additional pattern by embroidery or by shuttle embroidery, as in tapestry weaving; dyeing or printing after weaving. The Indian craftsman uses all five methods separately or together; and there is a very great variety of fabrics produced, from plain white silk to the elaborate and beautiful *kamkhwábs* worn by princes.

It is impossible here to describe the methods used, all contrived with extremely simple devices; the simplest loom has two shafts, two pedals, and pattern is only possible in stripes and checks. Then there is the four or many-shafted loom, weaving twills and twill patterns. In Burma this leads to the eight and twelve-shaft loom doing beautiful fabrics. Then there is the loom with the shafts replaced by cords, and varying combinations of cords worked by strings; there is the Dobbie, used chiefly for borders; and there is the elaborate loom in which each pair or set of threads is connected to a string, and combinations of these are pulled in turn by a boy, who picks them out by means of a series of loops put round each consecutive combination by the loom-setter. This method will give any elaborate combination required; when to it is added the complexity of separate border warps and border shuttles, of separate workers putting in embroidery with shuttles, you get the gorgeous and elaborate *kamkhwáb*.

There are other fabrics made by tying up the warp threads, dyeing the untied parts, and then so arranging them to make patterns; and this is a common device in India. Beyond this are the lovely embroidered fabrics of North India embroidered in floss silk or in heavy thread in a peculiar knot stitch; in these there is great artistic scope and full advantage is taken of it. I show you a few of the fabrics so made, only a very small number that attracted me specially; but the variety of design and texture in India is amazing.

The silk-weaving industry of India is large; it employs probably 200,000 people as weavers and 100,000 as twisters, preparers, etc. In the main the industry exists to supply the silk fabrics of the country, and in this there are

three principal classes—the silk *sari*, *dhoti*, and conventional dress prescribed by custom; the embroidered and fancy silk article mainly made in North India; the fancy silk piece made for wear in Burma, in which variety of design is the essential qualification.

The first is the backbone of the industry. In the Bombay Presidency, Madras, Mysore, Bengal, the Punjab, Nagpur, and Benares there is a weaving industry turning out goods of great value in the conventional garment of the Hindu. This absorbs much Indian silk and more imported silk. The articles are not piece-goods, but complete pieces ready to wear and in all qualities, from silk-bordered cotton to *saris* costing up to £20 a yard. The value of the cloths so produced, taking an average value of cloth as double that of raw silk, is near to £2,500,000; and it is on this demand, little influenced from without, that the industry mainly depends.

There is, secondly, the large trade in fancy silk goods, ribbons, fringes, ornaments, huqa tubes, and embroidered goods, made chiefly in North India. There is no means of estimating even approximately its extent or value.

Thirdly, there is the special market of Burma, which imports yearly raw China silk worth £140,000 and weaves cloth, but it also imports cloth worth £250,000 and wears it. The Burmese are peculiar in that they buy variety, not fixed patterns; they need bright colours, pink, yellow, and mauve in patterns and, above all, variety; so Japan and India export to Burma a great variety of piece-goods which make into *longyis* and *pasos* for daily wear. There is a remarkable industry in Rangoon in printing patterns from wood blocks on Japanese silk; the Burmese in this way get variety at a small cost and can get new patterns printed on whenever they tire of the old.

You will notice that I say nothing of ordinary piece-goods, of plain silks, of tabbys, satins, twills, suitings, spot and stripe silks, lining silks, and so on. There is a production for the big cities, but it is small, and nearly all that is sold is from Japan and China. The Indian craftsman can produce almost anything; in Madras and Burma he is learning new methods and producing new fabrics; but the home demand is so stable, so vast, so near at hand that the trade is mainly concerned with that. The export of Bengal corahs, plain silk woven in the gum from untwisted threads, is nearly dead, and there is not much now produced in India that would interest this country.

Let me now give you some figures, vague, inexact, but perhaps the nearest yet reached. The production of raw silk in India is of an amount near to 2,800,000 lb. of a value of Rs. 17,500,000 (£1,225,000). The export is now small, being that from Kashmir (200,000 lb.) and of Bengal, a very fluctuating amount; I omit eri, tasar, and cocoons entirely. There is a large export of waste silk, from £500,000 to £750,000. There is an import of raw silk totalling over 2,000,000 lb., practically all from China. Silk imported and produced is woven into cloth worth nearly £4,000,000 sterling. These figures are vague and uncertain, but not far out. There are some 370,000 people who rear silkworms and collect cocoons; there are over 250,000 who twist or weave and probably another 100,000 otherwise engaged. There are at least 50,000 persons engaged as dealers or brokers, and there are probably 180,000 looms engaged wholly or partly on silk.

In what relation is this industry going to stand in regard to this country and to the Empire generally? Are the spinning-mills of this country to use Indian waste and eri? Are the weaving-mills to use Indian raw silk? Will England produce and export the spun silk yarn so largely imported by India from Italy and Japan? Will Indian silk goods find a demand in England?

There are two points to bear in mind—the quality of Indian goods and the question of price. I omit the question of a preferential demand for products of the Empire. In business patriotism does not pay, and it is useless to expect India to supply England cheaply or England to pay more than she will, say, to Turkey or Hungary. The quality of Indian raw silk, waste silk, and cocoons is peculiar. The Kashmir is equal to good French or Italian silk and sells well in France, but for the rest Indian raw silk and waste silk is not of a quality suited to all uses.

This can be changed, and even now the new races of silk being grown are approximating to the qualities of France and could be used in England; but it is not as yet clear whether it would be to India's advantage to change quality and seek European markets.

My inquiry was done from the point of view of India, of the Indian silk rearer and silk weaver. I have not looked at the matter from the aspect of the English manufacturer, but if there is a demand for silk raw products from India this can be met, if India be told what is wanted. There is an opportunity now for the

English manufacturer to say plainly what he wants, what he can use, what he will pay. The British Silk Association might play a large part in this development; and, speaking from the Indian point of view, I hope the English user will come forward and help. I would also like to see English spun yarns replacing Japanese and Italian in India, though this hardly seems likely.

If extension of trade with India did occur it must not be supposed that development in India would be quick or easy. There are three great obstacles to development in India, the first being the condition of employment in India, the sweated condition of a great proportion of the workers, the unscrupulous grinding of the craftsman by the employer. Speaking quite generally, with full knowledge of the exceptions, I say that this is the great obstacle to development of any industry or production; and, unless it is tackled rightly, no change will be possible with the opposition of the capitalist and landowner, who desire no change in existing conditions.

The second obstacle is want of enterprise and of business capacity, and the want of ordinary commercial honesty. Very few natives of India will embark on exporting business or have the enterprise to risk their capital; very few will invest money in companies; and this leaves one to the European investor and capitalist. This brings one to the th rd obstacle, the enormous profits required by the European firm or capitalist in India, an amount so large that few industries can meet it. This puts India at once at a disadvantage as against Japan or China. It is well to see this clearly, and to realise that you cannot develop silk in India paying 25 per cent. on capital and be also able to compete with the Japanese or Chinese industry.

These are the great obstacles to any development, and they can be met. But if India is to set out to supply any of the requirements of the Empire there must be some means of knowing what these are; and this must come jointly from India and the Empire. It is perhaps not new to you that the efficient administration of India enables any branch of industry to be rapidly and successfully stimulated, but that is not so in England; and if the British Silk Association or any other body, private or official, wishes to stimulate the production in India of raw silk products or silk goods suited to England, much more must be done than has been hitherto. I wish very much, for India's sake, something real could be done; but I see no likelihood of it unless the conduct of such affairs is very radically changed, or unless some machine is created which does really and effectively bring together the needs of the Mother Country and the resources of this corner of the Empire. Finally, I would like to emphasise the utter neglect of the silk industry in the Empire, in marked contrast to its development by France in her colonial empire. In 1912 I urged the importance of developing a silk industry in the West Indies, climatically the ideal part of the world; but there, as in Africa, in Mauritius, in other parts of the Empire, we have done nothing. Perhaps such a statement is out of pla e to-day when I speak as from India; but the development of a silk industry in all suitable parts of the Empire cannot possibly hurt India, and in the future Empire-grown silk may become so large that the Indian product will be in real demand in this country. I hope this may be so, and I look forward to the time when Britain and the British will develop its silk resources that now remain undeveloped.

DISCUSSION.

THE CHAIRMAN (the Right Hon. Lord Islington, P.C., G.C.M.G., D.S.O.), in opening the discussion, said that the author, in his extremely interesting and fascinating description of the Indian silk industry, had not only shown the advantages that India could offer in regard to its maintenance and extension, but had pointed out the difficulties that must be overcome if that extension was to be realised, especially in the direction of providing raw material for export purposes. He gathered that the advantages to be obtained were very considerable, and also that, whilst the obstacles to be contended with, both physical and material, were formidable, they were by no means insuperable. It was common knowledge to all who were acquainted with the industrial system in India that the important silk industry had of past years retrogressed in some parts of India where formerly it was flourishing. Whilst that retrogression had gone on, the demand for silk throughout the world had steadily increased, and with the retrogression in India there had been a corresponding and conspicuous progress elsewhere, notably in France and Japan. The Government of India, realising the retrogression, and the opportunities that were being taken advantage of by other countries and were being lost by India, looked into the subject in 1915, and came to the conclusion that the best means by which an improvement might be ensured was that a thorough inquiry should be made into the industry as it was established in India. They accordingly very wisely invited the author to undertake the task and to make a report, which

he had already submitted to the Government of India, and which it was at the present time considering. It would be premature for him at the present juncture to divulge the specific recommendations made in that report; but he thought it was clear, from all the author had said in his paper, that if the important silk industry was to be revived and to play the part it should, in view of the natural conditions of India and in accordance with the increasing demand for the manufactured article of silk, it was necessary that very marked improvements on scientific and organised lines should be introduced. It was necessary that appropriate places should be found for establishing the industry; that a suitable and healthy breed of worms for cultivating the raw product should be ensured; that disease should be avoided by every scientific means, and, when present, checked; and that skilled and efficient management should be secured. In short, a general and marked improvement in organisation and in scientific method must be established at every stage of the industry if it was to play its part in India, by an extension on a large scale of export to other parts of the Empire in the years to come, in addition to its indigenous consumption. The author laid stress on the paramount importance, if India was to be regarded as a nursery for an important industry for manufactures in other parts of the Empire, that the producer and the manufacturer should be brought into constant touch with each other. It was essential that the producer in India should know the exact kind and quality that he must produce for the manufacturer to enable him to sell with profit in the outside markets of the world, and some form of co-ordination and organisation as between the producer and the manufacturer must be established for that purpose. He hoped the paper and the author's report to the Government would have the effect of increasing the production of silk in India to a degree far beyond anything that had been the case in the past.

MR. FRANK WARNER (President of the Silk Association of Great Britain and Ireland) said the author had made his audience completely acquainted with the methods of manufacturing silk in India, from the reeling to the final manufacture of fabric, and they were more primitive than he (Mr. Warner) had ever imagined they were. The methods connected with the growing of silk, its spinning, weaving, and dyeing, had vastly improved in every European State, and also in the Far East, particularly in Japan, and in view of what the author had said, and the slides he had shown, it made one feel how almost impossible it was for India to compete in her silk productions with other countries. He fully agreed with the author's statement that the interests of India must be considered first so far as the industry was concerned, and he thought it would be an immense boon to India if her productions were increased to such an extent, particularly of raw silk, that she became an important competitor in the world's markets. So far as climate was concerned, what applied to India in the main did not apply in the northern provinces of India, from which he had seen some very beautiful silk of recent years. Twenty-five years ago practically no silk was grown in Kashmir, although it was well known that Kashmir had been a silk-producing State for hundreds of years. In 1894 a small parcel of silk grown in Kashmir was sent to the India Office, which his father was asked to test, and it proved to be of the highest quality. As a result, the India Office invited Sir Thomas Wardle to go to Kashmir, and to do all that was necessary to start the growth of silk on a large scale. Everyone was very much indebted to Sir Thomas for what he did in that connection, and he also desired to mention Sir George Birdwood, who did excellent work. The export of silk from Kashmir now amounted to about 200,000 lb. annually, compared with practically nothing twenty-five years ago, and the question might naturally be asked, Why should not that increase be very much more multiplied? The quality of thread was finer in size and more even in quality at present than the first parcel sent to this country, but he was not sure that it was of equal strength, or that it had the same vigour and nerve. He believed the first parcel of Kashmir silk was grown from the indigenous worm, and if that was so it behoved those who took practical steps to develop sericulture in India not to cast aside the indigenous worm without giving it a thorough trial. Patiala silk, the first parcel of which came to this country about a year ago and was a very lovely silk, was grown from French seed, and in that connection one very important lesson had been learnt by the Patiala State by the successful growing of silk in Kashmir—namely, when the Patiala State decided to grow silk it engaged the services of a native who had graduated at the French silk school at Montpelier. When he was fully qualified he went to Patiala three years ago and started the industry, which thus began at a very high level of production. If high-grade silks could be grown in Kashmir and Patiala, why should not sericulture be carried on through all the northern States of India with the same measure of success? It was not desirable to bother about the other parts of India where the climate was not suitable, but only those parts which were suited to the growth of silk. The area of those States situated on the foothills of India was double the area of Japan, whose output was now the greatest in the world. Twenty-five years ago the world's production of raw silk was only 13,000,000 kilos, compared with 27,000,000 kilos in 1913, and

even that enormous production was not sufficient for the world's consumption. There was an enormous demand in the world for tasar silk, and it seemed a great pity that India did not hold her own in the growth of it. Eri silk might also be generally grown, not only in India, but in many other parts of the Empire. If, however, India was to compete in the great trade of piece-good production such as in China and Japan, there must be a great development in the present primitive methods of weaving. The British Silk Association, all through its career, had done what it could, not only for sericulture in India, but in other parts of the Empire, and they intended in the future to give their best attention to that part of their policy. They were encouraged to take a deeper interest in the matter because they believed that after the war there would be an Imperial Preference which would bring the Empire together and be the means of developing its resources.

Sir William Duke, K.C.S.I., K.C.I.E., said there was nothing more depressing than to watch the gradual decay of what had been a great industry, and for the greater part of his time in India that was his ill fortune. It was, therefore, with all the greater satisfaction that he heard the hope expressed by the author that the industry might still be revived. Thirty-two years ago the district in Bengal in which he was located was full of traces of an enormous silk industry, which was three parts dead and the other part dying. Two generations before a great commercial house used to lay out annually £80,000 on silk; but the whole of that trade had now gone. A filature which was then run by a European agency on the other side of the district had also gone, and there was now only one English firm which continued to reel silk in an adjoining district. Shortly afterwards the provincial Government took in hand the question of combating one of the great causes of the decay, namely, the pebrine disease; but their efforts failed, owing, he understood, to their attempting to apply it without sufficient scientific knowledge. They attempted to apply the system produced by Pasteur without adapting it to tropical conditions; but he was assured that, if it was properly adapted, Pasteur's system, or something of the kind, would give a supply of pure seed. Without pure seed and the eradication of the disease there was no hope for the industry. With regard to the economic situation, the author had pointed out that the same amount of silk exchanged for only one-third of the amount of rice which it did a generation or two ago. It was obvious under those conditions that a product which had failed to keep pace with the world changes in value must fail. Unless silk could command a better price it was useless to try to re-establish it. He gathered that the silk of which the author was then speaking was the indigenous Bengal silk, which was consumed entirely in India, and which was unsuitable for manufacture in this country. In that connection it occurred to some members of the Government of India that something might be done to improve the value and character of the Indian silk, and that by working on Mendelian lines it might be possible, by successful hybridisation, to get the merits of the valuable uni-voltine Italian silk into the multi-voltine Indian variety. If such a hybrid could be produced, the enormous advantage would be obtained of recurring crops in a climate where crops of silkworms could be reared during a considerable part of the year, and at the same time a silk of high quality. When the author's report was published it would be seen how far that was practicable. If it was practicable he thought the economic question would be solved, because if a silk of equal quality to the Italian silk could be produced it would command a price which would be sufficient inducement to the Indian growers to take it up again. Seven or eight years ago the Agricultural Department in Bengal made efforts to popularise the cultivation of eri silk; but after several years of effort the experiment failed, owing to the want of a market. Failures of that kind could be overcome by a combination of the producers and the manufacturers. Co-operation on the part of the growers alone was not enough; the manufacturers must also take a hand, and the buying organisation must be developed. If it was left to individuals it only resulted in every kind of failure; but a system could be successfully worked by organisation and co-operation as between the producer and the manufacturer.

Sir Louis Dane, G.C.I.E., C.S.I., said it was also his lot, during thirty-seven years' service in India, to see the great silk industry in Kashmir and the Punjab decay; but it was also his good fortune, before he left India, to see it re-established, and to play some small part in its re-establishment. The mulberry grows freely over the greater part of Kashmir and the submontane Punjab, and there was no reason why a large and important silk industry should not be fostered in that part of India; but, unfortunately, in the eighties the worms in Kashmir and the Punjab were attacked by pebrine, and the industry died out completely. Those were the unfortunate days of *laissez-faire*, when it was held that the Government ought not to interfere with private enterprise; but happily that most pernicious doctrine, as applied to India, was now being abandoned, and the Government was trying to do something to help the great industries, which would be the making of India. In 1896, with the able advice of Sir Thomas Wardle, a real attempt to establish the industry was made in Kashmir, where the climate was suitable, and where, in

the second place, the Durbar was sufficiently enlightened to spend some money on the attempt. Up to recent times the Finance Department of the Government of India was only a very closely organised audit department, and did not realise that it was impossible to make money in big industrial enterprises without spending money. Consequently the Government of India could not be induced, without years of effort, to spend anything to encourage an infant industry. Fortunately, in a Native State, if the advisers of the Chief could convince him that their views were sound, money could be found, and that was how the silk industry was really started in Kashmir. The difficulty of the pebrine disease was got over by importing disease-free seed or eggs from France and Italy. The growth of the indigenous worm was encouraged, but it was very difficult to get rid of the pebrine trace at the time, although now a considerable amount of indigenous seed was successfully grown. In 1901, when he was appointed Resident, an audit officer reported that the industry involved a loss and should be abandoned by the State. Happily he was able to get these orders reversed, and the experiment was continued. Without the assistance of the Maharaja and the Durbar it would have been absolutely impossible to have re-established the industry. At first the people were not anxious to take it up, because previously they had not made any profit from it; but in the long run it proved a triumphant success. The Durbar made a profit of £50,000 a year, and between eight and eleven thousand people, who otherwise, owing to the collapse of the shawl trade and the stoppage of grants of rice at favourable rates, would have been in a condition approaching starvation, now received excellent wages in the filatures. The 80,000 silk rearers realised as much for their cocoons as the whole land revenue of the tract. Altogether it had been a splendid thing for the people and for the Durbar, and it was a most happy illustration of what could be done by willingness to spend money on good advice in the starting of a new industry in the East. When he went to the Punjab as Lieutenant-Governor he endeavoured to revive the industry there. He called in the help of the Salvation Army and advised the States to take up silk-growing, and he was glad to hear that the effort made in Patiala had been so successful. Other Native States were taking up the cultivation, and if a certain amount of personal interest was taken in the matter and money was made available, the silk-growing industry in the Punjab had an immense future before it. If, on the other hand, before the industry was well established, the authorities for the time being said that things must be left to the ordinary rule of supply and demand, he was perfectly certain there would be no silk industry anywhere in Northern India. It was necessary to look after such an industry for the first five or six years and spend money on it—even to lose money on it. When the people appreciated there was a living to be made out of it they would take to it, and it would become a most valuable industry. It was a cottage industry which could be done at odd times by the women and children, and that made it all the more valuable. If British India would copy the methods of the Natives States to some extent, so far as they were wise, an immense deal would be done for the industries of India.

MR. A. JOHN SOLLY, representing the silk-spinning industry, said that previous to the war a great deal of silk was purchased from Bulgaria, Thrace, and Turkey, and the silk-spinners of this country desired after the war to replace those silks with silks grown within the Empire or by our Allies. For the growth of silk good climate and cheap labour were required. It was largely grown in Italy, France, and the Levant, and if the Italians could make a living out of it the Indians ought to be able to make fortunes. There was something radically wrong if Indians could not live by growing silk when Italians and Frenchmen could do so. His greatest hope lay in the awakening of the Government to its responsibilities in the matter, and also to an awakening of the people in India itself. He hoped there would be a great development in the future through the co-operation of the Government and the commercial classes, and by the education of the inhabitants of the distant countries in which silk was grown.

COLONEL C. E. YATE, C.S.I., C.M.G., M.P., emphasised the necessity of the silk industry being stimulated in India if it was to be successful. When he was Chief Commissioner of Baluchistan he did his best to help to stimulate the industry inaugurated by Colonel Showers in Kalat, and excellent silk was produced; but directly the stimulus was withdrawn the industry died down. The want of enterprise and business capacity among many of the natives, as stated by the author, was undoubtedly one of the reasons the silk industry in India did not flourish. He hoped that the Chairman would see that the industry was stimulated in every possible way, and he looked forward to the inquiries that were now being made at the Imperial Institute with very great hopes for the future.

SIR FREDERICK A. ROBERTSON, LL.D., in moving a hearty vote of thanks to the author for his interesting and instructive paper, said that Government help was very useful to such an industry as the silk industry, and it was worth while risking some money with the object of seeing whether it was one which the natives of India ought to be encouraged to pursue; but it was exceedingly dangerous to

press an unsuitable industry for which there was not a proper market. Although, therefore, he approved of Government help being given, he thought it should be very carefully watched. It might be the case that the Bengali knew a great deal better than the European when he gave up the cultivation of silk for rice; and if by growing rice he could make four times as much money as by growing silk, it would be a very bad thing to try to force him to grow silk. With regard to the question of the Native States having shown more enterprise in the starting of the silk industry, it must be remembered that they were in a position to apply an amount of pressure which no British Government could. The silk industry was, no doubt, paying in the particular district in which he had seen it, but whom was it paying? He thought some of those who had spoken had lost sight of the fact that the silk industry in Native States looked well on the surface, but that it could only be pushed with great care in India. It was only in those parts of India in which there were signs, not merely produced by official or governmental pressure, but signs coming from the outside commercial world that there was a demand, that the industry would pay. Encouragement and financial support in its initial stages were desirable; undue pressure was not. It was clear that the author and the Government fully shared these views, and this was the greatest encouragement to the hope that a successful silk industry might be established on sound lines.

MR. W. COLDSTREAM, I.C.S. (retired), seconded the motion, which was carried unanimously.

PROFESSOR H. MAXWELL-LEFROY, after thanking the audience for the cordiality with which they had passed the resolution and Lord Islington for his kindness in presiding over the meeting, said that those present had been more or less led to hope that other parts of India could rival Kashmir in its production of silk; but it must be borne in mind that in exactly the same time in which the Native State had built up its silk industry, in the British district bordering on Jammu, although it was larger than Jammu, the silk industry there was ten times less in extent than in Jammu. It was no good blinking the fact that the reason for that was that methods were used in the Native States which could not be applied in the British district. There were at the present time eighty thousand rearers in Kashmir who were satisfied and who liked the industry; but it must not be forgotten that they were paid only one-third of the market value of the cocoons, and the difficulty had arisen that a native who could smuggle his cocoons over the frontier obtained three times the price for them that he did in his own State. It was impossible to adopt Kashmir methods in British India, and he therefore did not wish the audience to go away with the idea that a large industry could be developed in India on the lines of Kashmir. Sir Louis Dane had referred to the indigenous Kashmir worm. The worm that was now being reared in Kashmir was not the original indigenous worm produced in Kashmir, but was produced from French stock. The original indigenous Kashmir worm was so nearly extinct that they had not been able to get any, but they were trying to do so.

MR. WILLIAM COLDSTREAM, I.C.S. (retired), writes :—At the conclusion of Professor Maxwell-Lefroy's paper on Indian silk I mentioned that I had conducted a series of experiments in the domestication of tasar silk in the Punjab. My experiments were reported officially at the time. (See the Agricultural and Horticultural Society's *Journal*, Calcutta, Vol. IX. Part I.) From 1876 to 1881, when Deputy Commissioner of Hoshiarpur District (in 1880 at Lahore), Punjab, I attempted to domesticate the ***Antheræa sivalica.*** I collected the wild cocoons from the villages, and kept them in bamboo cages till they were ready to burst. The moths hatched out in June or July at the beginning of the rains. The eggs obtained were placed in flat basket trays, and the worms were, when a few days old, placed out in the open on beri trees (*Zizyphus jujuba*). An attempt to feed them by hand ended in failure. The beri proved to be excellently suited for the purpose, as, after its leaves had been browsed down by the worms, it sent forth in a few days an abundant flush of fresh leaves. The Sáwani plant (*Lagerstrœmia Indica*) was also tried, but with less success. The beri is evidently the Punjab leaf for the tasar worm. The worms browsing on the tree in the open arrive at full growth in twenty-five to forty days, and forthwith begin to spin. I planted close to my house, at Hoshiarpur, a little grove of *beris*, the trees only a few yards apart. They established themselves easily, and in three or four years were ready as feeding-grounds for the worms, some of them reaching by that time a height of ten to twelve feet, and becoming quite well developed. In the Punjab, groves of grafted or Kabuli *bers* are very common. The trees spread thick and low, with long pendulous branches arching over to the ground, and thickly covered with leaves. Such groves could, I believe, most easily be converted into tasar plantations. The trees are not high, so that the watcher's task would be easy, and the supply of succulent leaf is abundant; and as the *beri* crop is over early in the year, the trees serving in autumn as pasture ground for tasar worms would not, I believe, impair their fruit-producing powers. Several hundred worms on a tree soon strip it of its leaves, for the worms are very voracious, and when full grown are some five to four inches

long. I have taken more than two hundred cocoons raised on one of my own little beri trees. Though the reeling of tasar is usually considered to be somewhat difficult, I found little trouble in reeling off the silk from the cocoon. I got for the work one of the silk-weavers from the neighbouring district of Gurdaspur. He reeled off a clean lustrous thread of four strands, keeping four cocoons bobbing in a dish of boiling or very hot water in front of him. I do not believe he used potash or anything but the hot water to dissolve the natural cement. The man worked at the rate of about fifty cocoons per diem, yielding about two and a half *tolahs* of silk. Beautiful tasar wool or floss was also turned out, the cocoons being teased, not reeled out. This tasar was clean, soft, and elastic, like cotton-wool. On the whole, though I cannot say I have absolutely ascertained the conditions of success, I have seen so much in the course of my experiments as to make me believe it possible that a kind of cottage industry of rearing tasar, requiring absolutely no capital, and capable of being conducted by women and children, may some day arise, if pains are taken by experiment and the offer of rewards to ascertain these conditions and to introduce the industry to the notice of the natives. The wild tribes of Central India rear the cocoons; why should not the cottagers in the Punjab hills? The insect is indigenous in both places, and its food can be provided to any extent by planting at almost no cost. "One great objection," says Sir George Watt, "to the development of the tasar silk industry is the imperfect and faulty system of Indian reeling. This fact is at once established by the published figures of the tasar reeled fibre, the Italian or improved fibre yielding three or four times the price of the ordinary native-reeled silk" ("Dicty. Economic Products," Vol. VI. Part III. p. 151). It has been suggested (see Hailey's "Monograph on the Silk Industry of the Punjab, 1899") that the ease with which my silk was reeled might perhaps be accepted as an indication that the *Antheræa sivalica* would yield good results under the improved reeling process, and that it would be at all events interesting to ascertain whether this were or were not the case. It has been considered a matter for regret that no successor carried on my efforts to cultivate the *Antheræa sivalica*. My attempts at Hoshiarpur came to an end when I left the district. The little grove of beri trees planted near my house to supply food for the worms was cut down by the owner on my transfer (District Report, 1899).

THIRTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 7th, 1917; EDWARD DENT, M.A., Member of the Council, in the chair.

The following candidate was proposed for election as a Fellow of the Society:—

Ledgard, Sir Henry, Langdale, Farnham, Surrey.

The following candidate was balloted for and duly elected a Fellow of the Society:—

Willis, Henry S., Weardale House, Wearhead, Co. Durham;

and as an Honorary Corresponding Fellow:—

Belaiew, Colonel Nicholas T., C.B., Chemical Laboratory, Michael Artillery Academy, Petrograd, Russia.

The paper read was—

GERMAN METHODS.

By JAMES HARRIS VICKERY, LL.B.

It is not intended in this paper to attempt anything like an exhaustive treatment of the vast subject of German methods. It would require a specialist in each of the subjects to accomplish that task. It is only intended to give occasional glimpses at these methods as they have appeared to me from time to time during a professional residence in that country extending over a number of years.

I.—DIPLOMATIC.

My first experiences of Germany may not be without some interest, since they refer to a period during which other countries, some of whom are now belligerent and some neutral, were then at war. Shortly after my arrival, in the summer of 1897, the Spanish-American War broke out, and I was able to observe the conduct of Germany in the *rôle* of a neutral professing friendship for both belligerents.

The salient feature of the German attitude, more especially of the commercial and industrial classes and of the people at large, was hostility to the United States. This was an interesting revelation. Tangible reasons for this hostility did not appear to exist. The official attitude was correct. But the spirit of envy and enmity seemed to permeate the very atmosphere; it cropped up continually in private conversation, and found daily expression in the newspapers of the metropolis; indeed, the German newspapers of that day seemed to vie with each other in the art of garbling and mutilating news of the conflict so as to create popular "Stimmung" or feeling in favour of Spain and against the ever-growing Republic of the New World.

It was, in fact, my first experience of that particular kind of joy which the Germans themselves so appropriately term "Schadenfreude," which may best be translated as "pleasure in the discomfiture of another."

Such was the political atmosphere in Germany when the news came of the action of Admiral Dewey in Manila Harbour, and reports began to be flashed over the world that it would probably have come to a conflict between the American Admiral Dewey and the German Admiral Diedrichs had it not been for the fact that there were certain British battleships in the vicinity with decks cleared for action, which exercised a restraining influence on the meddlesome tendencies of the German admiral.

Boer War.

Two years later the Boer War broke out. Again Germany played the *rôle* of a professed neutral, but it was obvious, from the very first, that the feelings of hostility engendered by this conflict were much more intense than in the case of the Spanish-American War. In fact it was evident from the beginning that practically all classes of Germans appeared to have been holding in reserve a reservoir of hatred of Great Britain. There is no purpose in going further into this matter, which is now ancient history, and I only refer to it because it constitutes a further example of German conduct as a neutral, the outstanding feature being that, although the war was no concern of hers whatever, and although one would naturally have looked for a lofty, philosophical and judicial attitude at least on the part of her eminent professors and publicists in dealing with the questions to which it gave rise, these same professors and publicists, the daily press, and even the more serious scientific and learned organs, all contrived in one way or another to sink to an extraordinarily low level of partisanship, characterised more by enmity to Britain than by friendship to the Boer Republic. I remember especially a petition signed by some seventy university professors which was circulated at the time and which, in its purported statement of fact, contained a veritable travesty of the real causes of the conflict such as I had thus far not seen elsewhere.

Peace Conference, 1899.

If the conduct of the German professors and savants, and of the German people in general, was a big disillusionment to one who had been taught to regard this nation as possessing almost more than the usual sterling virtues, the conduct of official Germany at the first Peace Conference at the Hague in 1899 was calculated to complete the evidence of what was and is an undoubted fact—namely, that there has long existed a vast chasm between the political ideals of the German and English speaking races.

I am only referring to the first Peace Conference for the purpose of pointing to one episode illustrative of German diplomatic methods. It is rendered all the more interesting on account of the recent peace overtures of Germany and of the "Peace without Victory" speech by President Wilson which has been variously, and to some extent unfavourably, interpreted in the Entente press. The episode to which I am about to refer has not, so far as I am aware, been made public and belongs perhaps to the secret history of the Conference.

When, in obedience to the Czar's rescript, representatives of the nations gathered at The Hague to deliberate on the subject of disarmament, etc., it was immediately realised by the British and American representatives that the Conference would be a fiasco if it did not devote its attention to other questions more ripe for solution than that of disarmament.

The British and American representatives decided that, before there could be talk of disarmament, some practical effort should be made to dispose of international disputes by processes more nearly akin to those practised in courts of law and boards of arbitration—in short, that an attempt should be made to establish the beginnings of a real international law to be administered by a real international court. The French delegates heartily supported the project. The late Lord Pauncefote, as head of the British Delegation, took the initiative in the drafting of the scheme; Dr. Andrew D. White, as head of the American Commission, devoted his great influence and talents towards tempering the scheme to the circumstances of the New World. Prince Münster, as head of the German Commission, brusquely refused to support it, or to co-operate in any way in the matter. He regarded it as contrary to German interests and as an infringement upon diplomatic prerogative. All efforts to bring him to reason failed; all representations to the effect that he was planting himself squarely across the current of peace tendencies of other leading nations were in vain; he remained hostile and obdurate. Realising that it would probably be impossible to achieve any useful result in the face of the continued hostility of the German representative, Dr. White wrote an impressive and urgent letter to the German Foreign Secretary and delegated another member of the Commission to present this letter in person, and to make it plain to the German Foreign Secretary that, if the earnest efforts of the Conference to accomplish any useful work in the direction of diminishing the cause of war

and furthering the interests of peace should be frustrated by the German representative, the whole Conference would be a fiasco, and the other nations would hold Germany responsible for having wilfully wrecked it.

As a result Count Münster was finally instructed to withdraw his opposition. The other nations, under the leadership of the British, American and French representatives, completed the work which resulted in the establishment of the Tribunal of The Hague—an institution which one day may well fulfil the hopes of those who laboured to establish it. In any event it will remain as an outstanding fact of the history of those days that "peace-loving" Germany unmistakably revealed herself at that Conference as a determined opponent of every attempt to provide a peaceful solution of international difficulties by means of a tribunal or by arbitration.

It would be a grave mistake to assume that President Wilson was unaware of this fact when he recently declared in substance that the aspirations and peace aims of the two groups of belligerents, as respectively enunciated by their own statesmen to their own nations and to neutrals, appeared to be the same. President Wilson was doubtless well acquainted with the despatches on file in the State Department from the American Commission—which, by the way, contained two brother university presidents—and well knew that America and Britain not only *professed* their adherence to the cause of peace, but *worked* in harmony with those professions to establish the International Tribunal and to further the cause of arbitration; while Germany, although likewise professing her love of peace, refused her co-operation as regards the project to establish the tribunal and opposed arbitration.

In the light of these facts, President Wilson's recent utterance takes on a new meaning and significance as to the manifest inconsistency of German professions and practices. President Wilson's peculiar phraseology will, it is hoped, not have escaped the attention of the German Foreign Office, for, in the light of the developments of the last twenty years, it is susceptible of no other meaning than that of a delicately veiled challenge to Germany to bring her practices into harmony with her professions.

Relations with Canada.

Another minor diplomatic episode may not be without interest at the present time. As is well known, when Canada devised a tariff based upon reciprocity to the benefits of which England, by reason of her free trade policy, automatically became entitled, Germany sought and insisted upon having a like advantage in the Canadian market, on the ground of the most favoured nation arrangements. Canada replied that Germany could have the same treatment as England if she in turn granted the same treatment to Canada as England. The question was, therefore, one between treaty rights irrespective of reciprocity (which was Germany's contention), and reciprocity as a consideration for preferential treatment (which was the Canadian contention). As Canada insisted on maintaining her policy, the most favoured nation arrangements were terminated by England at Canada's request. Such open evidence of the tendency of Motherland and Colony to draw closer together was regarded in Germany as little short of a crime, and Germany promptly commenced the now familiar process of strafing the culprit. Extra duties were placed upon Canadian products. Canada promptly replied by imposing a surtax on German products. As a result of these measures of reprisal German-Canadian trade diminished almost to the vanishing point, while Anglo-Canadian trade and commerce between Canada and the Republic to the south continued to grow in ever increasing volume. After a number of years it dawned upon the German mind that the process of strafing Canada had only resulted in depriving the Germans themselves of the Canadian market, to the not inconsiderable advantage of British and especially of American manufacturers.

Proposals were then made through the German Consul-General in Montreal to the Canadian Government, which resulted in the mutual removal of the prohibitive surtaxes, and established favourable reciprocal treatment with reference to a number of specific commodities and products of either country.

Canada thereupon sent a special Trade Commissioner to take up his residence in Germany, and there to look after the commercial interests of Canada, as German interests were being looked after by the German Consuls in Canada. One would have thought that the Germans would naturally have seized this opportunity of expressing their goodwill and satisfaction at the inauguration of a new era of friendly commerce, and that they would have shown this first Canadian Trade Commissioner to Germany similar attention and courtesies to those which had been constantly shown to German Consuls in all parts of the Dominion

Nothing of the kind happened. The Canadian official was required to present himself to the police for registration, which he did. Presently, after he had taken an office in one of Berlin's leading streets, he was presented with a form and required, within such and such a time, to make a return of his property and income for the purpose of taxation. The Canadian Commissioner replied in substance that, inasmuch as his position was analogous to that of a Consul, he hoped that the same courtesy would be extended to him as was enjoyed by the German Consuls in Canada. The Germans replied that he was not a Consul, and that he must declare his income for taxation, otherwise he would be strafed. A number of communications passed, in which the Canadian Commissioner was at pains to point out his inability to comply with the German demand without the sanction and instructions of his Government, and also that to transmit the German demand to his Government would produce an unpleasant impression and tend in some measure to undo the work of reconciliation so happily begun.

The Germans remained obdurate. Finally, the Canadian Commissioner informed them that he refused to make any return unless and until instructed by his Government, and that if any attempt were made to assess him and to collect the tax by force as they had threatened he would close the office and leave the Empire. This was in effect an ultimatum. In the sequel the Germans ungracefully retreated, and without a line of regret or apology informed the Commissioner that it would not be necessary for him to make a return of his income.

The episode is of no consequence in itself, but it is one of the numerous unpublished examples of German blundering and boorishness in dealing with other peoples—a method of official conduct which is characterised by want of consideration, and by inability to appreciate the bad impression produced on others by the blind and clumsy insistence upon German rights and German rules as a sort of standard to which all must bow down irrespective of the equities of the case or of the psychology of the parties.

II.—Education and Science.

Much has been said and written about German educational methods. I shall not attempt to go at length into this much traversed subject, but one or two points deserve more consideration than are generally given to them.

A few years ago one of the American Exchange professors, during his sojourn in the German capital, gave a lecture on the subject of educational methods. He pointed out to his hearers some essential differences between German, British, and American universities as they appeared to him. The British universities, he said, still continue to exercise a strong parental influence over the students and to devote much attention to the process of character building, to which process the extensive sport activities of the British students made a not inconsiderable contribution. In Germany, the student was left largely to his own devices in private life, but the scientific instruction available to him was ahead of that afforded by the British institutions. This difference was mirrored in the very words of the two languages. The British *educated*, the Germans *instructed*. The word "Unterricht" *did not* mean nearly the same thing as education, and he pointed out that the better American universities sought both to educate and to instruct, in order that character might not be sacrificed to knowledge.

This has always seemed to me to embody an essential truth. The evil reputation of the Germany of to-day is not due to any want of knowledge but to a want of character, and in the long run character will prove to be the more valuable of the two attributes.

Another difference of great importance may be here referred to—indeed, it cannot be too often referred to, because it is one point upon which we have been most remiss. I refer to the intimate connection between scientific teaching and research and the commerce and industry of the country. It is the habit of the Germans to refer to the English as being a "practical" people. In point of fact the German has been much more practical in the matter of turning scientific knowledge to account. With all his boasted idealism he has long since ceased to follow scientific research purely and solely for the love of the thing; he has been reared in a frugal, economic world, and has been taught that if science possesses any practical value it would be an unpardonable violation of an economic law to allow that value to go unexploited. As a result the university and Government laboratories are closely linked up with the factories and workshops of the nation. The industrial and commercial value of science and the Imperial recognition of the indispensable character of the scientist have had the effect of elevating scientific achievement both in theory and in practice to a position relatively higher than in any other country. The avenues by which scientific knowledge and discoveries are

transmitted from the universities and laboratories to the centres of industry, there to be practically applied and commercially exploited, have not lowered the tone of the scientist, but raised the tone of the industries.

It is impossible within such small compass to go into the details of the German system of education, the study of languages, the technical and commercial colleges, the continuation schools, and the like. These are details. I am more concerned with the spirit behind this development.

A few years ago the late Joseph Chamberlain asked us to *think imperially.* We have commenced to do so. In Germany not merely one man as a voice crying in the wilderness, but a thousand voices, from the Kaiser downwards, have been crying in chorus—*think scientifically, act scientifically.* This high patronage of science has been largely instrumental in breaking down the absurd old class distinctions between the professions and the trades. The idea that a lawyer or a doctor stood upon a higher plane than a mere business man never did have any justification either in theory or fact in a properly constituted social state. Ordinary commercial pursuits were mistakenly regarded as entirely outside the field of science, and even though the industries might lay hold upon this or that scientific truth or discovery and commercially exploit it, that did not justify the industrialist in regarding himself as being upon the same high plane as the professional man. This idea was inevitable so long as the scientific field remained restricted to pure science, to science for its own sake as a complete end in itself. But when it was realised that science could only be fructified for the benefit and uplifting of the human race being *practically applied* in all branches of human activity, in commerce and industry as well as in law and medicine, science itself became united and expanded into connected theory and practice with the result that, instead of being debased through its practical connection with commerce and industry, the latter were elevated to a scientific plane as high and as meritorious as that of the so-called professions.

This, I submit, is the essential truth of the matter. We in this country are now recognising that truth and putting it into practice. There is no need of our copying German methods, for if we once recognise the underlying truths of scientific development, both in theory and practice, we shall be able to work out the methods of fruitfully applying the discoveries of science and to devise the means whereby the trader and the industrialist may be elevated to honourable recognition.

III.—Social.

Certain social institutions in Germany have long deserved greater attention than they have received at our hands. Those to which I am now about to allude belong to what may be called *stock-taking processes*, and they constitute a most important factor in that science of organisation of which the Germans claim to be masters.

The foreigner visiting Germany, either for purposes of pleasure or of business, who has found it advisable to go into lodgings or take a flat, has usually been disagreeably surprised to receive a visit from the police with a request to present himself forthwith at the police-station. This is popularly attributed to some special desire on the part of the German authorities to exercise more than the usual degree of watchfulness concerning all foreigners within the Empire as a measure of political and military safety. That is undoubtedly one of the objects so far as foreigners are concerned, but its main purpose is to see that the process of stock-taking is duly and thoroughly carried out even in the case of foreigners. These stock-taking processes apply equally to all persons, whether subjects or foreigners; only the extent and kind of such stock-taking is varied according to the circumstances. Thus, there are three processes of registration.

1. *Civil Registration*, which applies to subjects and foreigners alike.

2. *Business Registration*, which requires that all persons, firms and corporations doing business in Germany, or coming under the definition of *merchant*, shall be properly registered in the business register which is kept by the local or district court having jurisdiction in accordance with the provisions of the commercial code. This business register is divided into different divisions according to the nature of the person, firm or company to be registered. The stock companies, the limited companies, the societies in commendam, partnerships and individuals, whether doing business in their own name or under some other style and firm, are required thus to register. No distinction is made in this respect between German subjects and foreigners, excepting that in the cases of German branches or foreign concerns special items of information

concerning the constitution of the foreign concern are called for in addition.

In the register itself, provision is made for special entries to show names and addresses of the proprietors of individual firms and partnerships, and in the case of companies the names and addresses of the directors, supervisors and managers, and in all cases firms are required to file a statement accompanied by specimen signatures showing the person or persons who are entitled according to law and according to the articles of the partnership or company to sign the firm or corporate name with binding legal effect. Changes in ownership, in boards of directors, supervisors, and managers, are chronologically recorded. The register is open to public inspection and certified. An abstract of the entries can at all times be had on application on payment of the folio fees which, in the average, amount to between 6*d.* and 1*s.* Under this system partners can be sued in the partnership name, and the certified abstract from the business register is evidence of the constitution of the partnership.

I could give many other instances of the utility of this register, but the main point to be kept in mind is that it furnishes a uniform and complete registration of all persons, concerns, and corporations engaged in commerce and industry in the Empire. It thus constitutes a register which, by way of comparison, would represent more than a combination of the Companies Register at Somerset House and the new register to be kept under the recent Business Names Act, because it also includes all individuals and partnerships doing business in their own names.

3. *Service Registers.* — Then there are the special military and naval registers, which are a strictly militant institution. In these are recorded down to the last detail the personal histories of all those belonging to the army and navy. In a sense these service registers are based upon the civil register, because the latter furnishes the necessary data according to which the military and naval authorities keep track of those young men approaching service age. Thus the civilian register and the military and naval registers contain at all times, both in peace and war, an exhaustive statistical statement of the man power and capacity of the Empire. Moreover, these registers require that, instead of merely general indications of trades, professions, and the like, the persons subject to registration shall state explicitly their particular trade, profession, or calling. Thus, the general term "engineer" is not sufficient; the specific kind of engineer must be given in detail. These registers, therefore, may also be said to contain continually up-to-date statistics of the brain power of the nation.

Census.—Another form of stock-taking is that of the census. The complete civilian register of men, women, and children within the Empire, with their exact addresses, and with the compulsory entry of all changes of address, makes it possible with a minimum of cost and delay to distribute the necessary census forms to be filled up on the date appointed for the actual taking of the census. The legal obligations imposed on the subject to assist and co-operate in the taking of the census are cumulative. A householder, *e.g.*, is required to see that all persons comprised in his immediate family as well as all persons in residence in the building of which he is the owner or proprietor shall properly fill in the returns.

As a result of this system the taking of the complete census of the Empire is accomplished in a period of twenty-four hours, and during that period every person is required to make the return, no matter where he may be, whether in a hotel, in a railway carriage, in ships at sea, or at work in the fields and mines.

As a recent example of the value of complete registration during the war, I would mention that the German Imperial Gazette, towards the end of last year, contained a proclamation requiring a complete census of the nation to be taken in the twenty-four hours between November 30th and December 1st, 1916, and the forms, which had been previously distributed on the basis of the civilian register, were accompanied by additional forms calling for a complete enumeration of horses, cattle, sheep, goats, and other animals, and of all geese, ducks, turkeys, and poultry belonging to the individual subjects of the Empire. I believe that this is the first time in the history of human institutions that a complete census of man, woman, beast, and bird in an Empire of nearly seventy million inhabitants has been accomplished in the incredibly short space of twenty-four hours and without the devising of any special machinery for that purpose beyond the ordinary functions of the police with the co-operation of the subjects themselves.

Compared with this example of scientific stock-taking, I fear that most of us must concede the fact that the National Registration Act of 1915 is but a poor example of British administrative thoroughness.

I ought not to close my reference to this subject without pointing out that the civilian register is of the utmost value as a means of controlling the administration of the income tax and other tax laws. Every person is required to make a tax return. Some do not do so, but those who do not are assessed and lose the right of appeal. None escape, because the completeness of the civilian register makes it possible to assess all those who have failed to make the declaration required by law.

To give one example of the thoroughness with which the tax-paying capacity of the people is exploited, it may be pointed out that prior to the war there were several hundreds, perhaps even thousands, of English goverresses in various parts of Germany. Their annual incomes on the average would be about £40 to £50, or 800 to 1,000 Marks. Incomes up to 900 Marks were exempt, but the German tax officials reasoned thus: These English girls get free board and lodging in well-to-do and rich families, the value of which would amount on the average to another £50 per year, equals £90 to £100; deduct the exemption of £45, and there remains a taxable income of £55. In this way these poor English girls have for years been required to contribute twenty Marks per year towards the Imperial revenues. If the many thousands of Germans and other foreigners who have resided in this United Kingdom year after year had been as thoroughly card-indexed and taxed, a very considerable amount would have been secured for the British Treasury.

There is still one other point in connection with this stock-taking process which is of great importance—first, collectively, in determining the man capacity of the nation, and, individually, in forming an estimate of the character and ability of the individual, and that is the custom of issuing certificates and testimonials covering the school period of the German youth and their subsequent business activities. These papers are collectively known as "Zeugnisse," or testimonials. A boy or man seeks employment; his first step is to produce his papers which show what education he has received, what technical instruction he may have had, the character of his conduct, the situations which he has occupied, the satisfaction which he has given; in brief, whether young or old, his "successes in life," and, frequently read between the lines, also his failures in life. A man seeking employment without the corroborative evidence of such papers is lost, figuratively speaking. These papers constitute his recorded self; if he is not on record, he practically does not exist. Thus, a poor person seeking to enforce some right at law, and claiming the advantage of the provisions for suing *in forma pauperis*, is required to produce an official certificate of good character, and such certificate is based, not upon the testimony of friends and relatives, but upon his recorded history in the custody of the authorities, and if that record is not good, the courts may deny him the advantages of legal aid.

IV.—German Industrial Syndicates.

It is not my intention to attempt anything like a detailed description of the German industrial syndicates. Professor Macgregor has already dealt with that subject in a most admirable and lucid manner. There are, however, certain phases of that question which possess for us a peculiar interest at the present time, when sovereign necessity is forcing us, as we have never been forced before, not only to work, but to do so subject to strict governmental regulations. We are, at the moment, a Socialist State, conducting many nationalised industries, and it is altogether likely that certain principles and practices of paternalism in government will remain permanently as a result of the war.

The main difference between British and German industrial syndicates consists in the fact that, generally speaking, the basis of the one was *capital*, that of the other was *output*. The same is true of the American trusts. In the popular mind, trusts and combines are synonymous with money power. Both in Britain and in America the freest possible scope is given to individual initiative; while, on the other hand, the governments have hitherto not developed greatly in the direction of nationalising industry. Quite the opposite is true of Germany, where the principle of nationalisation has been applied to a much greater extent. Now it is obvious that the more the industrial field is invaded by the State the smaller will be the remaining extent of territory open to exploitation by private enterprise. Consider for a moment what would be the difference between, *e.g.*, the Standard Oil Company with and without railways. Railways are privately owned in America and nationalised in Germany. A capitalist group can secure the control of a privately-owned railway and, although it is a public-service company, it can nevertheless in a thousand ways be so administered as to favour the primary objects of the controlling capitalists. In Germany that is impossible. Where private companies perform public services.

there is always a potential danger of their being diverted from considerations of public welfare to considerations of private interest and advantage, even under systems of strict control.

The point which I wish to emphasise is, that there are three relationships between the State and the subject: (1) Parental control, or that which is exercised from above; (2) competitive control, or that which is exercised laterally; (3) partnership control, or that which is exercised from the *inside*. In America, where there are very few nationalised industries and great individual initiative controlling vast sums of capital, the tendency to abuse the almost limitless opportunities for industrial combination and for the use of capital called for corrective measures, which were, in fact, devised and applied from above in the shape of the Sherman Anti-Trust Act, according to which any industrial combination falling within the definition of the Act could be regarded as a plot or conspiracy against the commonwealth.

In Germany the State itself is an *industrialist*. It runs the railways and canals, the letter post, the parcels post, the collect-on-delivery system in connection with the above, and the post-cheque system of banking, the telegraphs and telephones. It also controls the Imperial Bank as the institution governing the money market by means of its so-called "Bankpolitik," or monetary policy, which it formulates and administers. In the important domains of transport and banking the State thus occupies a position in some cases equivalent to that of a *competitive industrialist*, and is therefore able largely to influence the policy and practice of the industrial syndicates or cartels in the direction of the national interests.

Where there are Government-owned and controlled works in various branches of industry there exists a direct lateral control through competition, and, since the Government itself is frequently the chief consumer, the competing private industries find it more to their advantage to retain the goodwill of the Government as a customer than to incur its displeasure as a competitor. We can see these processes in operation in our own country at the present moment. The British Government has become an industrialist, and is manufacturing all kinds of munitions of war; but it also takes the output of private concerns. It is therefore in a position to know what the product ought reasonably to cost, and, in the event of inflated prices, to exert a corrective influence.

In my opinion the most interesting and effective form of control by the State over the larger industrial syndicates and cartels is that which may be described as *partnership control*. The German company laws, especially the comparatively new law known as the Limited Company Act, are based upon the principle of freedom of contract ("Vertragsfreiheit"), and hence individuals, partnerships, joint-stock and other companies, may become members of a new company by executing the contract of association. Many of the German syndicates are formed under this special Limited Company Act, which provides for a very elastic constitution that may at will be made as simple as a partnership agreement or as complex as the joint-stock company. The purpose of such a syndicate is to apportion the voting power in accordance with the turnover. Every individual, firm, partnership, or company, through membership, acquires a corresponding *voice* in the new company, so that the company in general meeting represents an *industrial assembly* in respect of the industry in question, or of so much of it as they collectively represent. If the Government is engaged in the conduct of works in that industry, it may either remain an outsider, and therefore a competitor in the ordinary sense, or it may come into the syndicate and thereby become a *partner* in the common undertakings and objects. As such, it naturally takes part in all the deliberations and in all the measures devised to determine and fix prices and regulate output.

There are other cases where the Government was deeply interested in the output of a syndicate, as, *e.g.*, where the Government was the chief buyer, and as such might be unwilling either for political or other reasons to pay the syndicate price. In such cases the Government frequently nominated a Commissioner to sit on the Board of the syndicate for the express purpose of watching the Government's interests as buyer, and securing preferential treatment in the national interests. In still other cases, the Government Commissioner was delegated to watch foreign competition and to study and even supervise the various forms and methods resorted to for dumping surplus products on foreign markets.

The above and various other phases of the political situation and industrial development serve to explain why it is that, notwithstanding the vast extent of the syndication of the industries in Germany, it has not been found necessary to pass special acts or resort to other

forms of exceptional legislation, similar to the Sherman Anti-Trust Act in America, in order to prevent the unrestrained syndication of industries from developing into intolerable evils, endangering both the national welfare and individual freedom.

It has long been recognised in Germany that the syndication of industry is in itself a perfectly legitimate and legal process, and that it could only become illegitimate and illegal by being directed towards the attainment of objects which were subversive of the rights of others or contrary to good morals or public policy—and in such cases the existing law of the land afforded the proper remedy. Thus, if a syndicate were formed for the purpose of forcing a competitor out of business, or for the purpose of cornering the market, or in order to extort exorbitant prices from the consumer, that constituted an offence against public policy and against the provisions of the law governing unfair competition. But if its main objects were to secure greater efficiency by eliminating waste, diminishing the cost of production, regularising supply and demand, preventing needless fluctuations by apportioning and limiting output and fixing prices in order to prevent working at a loss and unemployment, it was deemed to be pursuing objects which in themselves were in harmony with law and with public policy.

It is due in the main to the closer identification of the State in its character as a "captain of industry" with the individual industrialist that the latter, whether alone or combined with others in the form of a cartel, has been influenced to look upon each individual industry as a part of the industrial activities of the whole Empire which, collectively considered, constitute one of the main foundations of that "Deutschtum," or German hegemony, on which the continued growth and progress of the whole Empire, and therefore of every individual German, were believed to depend.

It was often said that in America, *e.g.*, there were only two factors present to the minds of the trust magnates, namely, themselves and their competitors, and that it was the chief purpose of the trust to eliminate the competitor either by killing him without consideration or by swallowing him for a nominal consideration. But in Germany it was said that there were three factors, the third one being the State itself whose welfare had to be considered, and that if any syndicate exhibited a pronounced tendency to forget the claims of the State, the State itself would jog the memory of that syndicate in some one or more of the many and subtle ways in which the Government can effectively impress its will upon the subject. This process is rendered all the easier on account of the inborn attributes of respect for authority and for the principles and practice of discipline, obedience, and organised effort infused into all Germans as a result of universal military service.

Some phases of German syndication of industry hardly seem appropriate to our ideals and system of government, but there are other phases which, I am persuaded, would well repay further examination. Under that most absolute of all monarchs, necessity, Government ownership and control have made enormous strides during the war. We are living in an epoch of temporary State Socialism, and have embarked on huge enterprises on the basis of the nationalisation of industries; but, in so doing, industrial kings and merchant princes have been impressed into the Government services, and have thus at least become partners in the management. There will surely be a reaction after the war, and the old question of nationalisation or Government *versus* private industry will be revived. Also in the not improbable event of a change in the country's fiscal and trade policy, there will arise, according to some people, the danger of the consumer being exploited by huge trusts and combines to grow up under the fostering influences of a tariff and customs duties which will restrict both foreign and domestic competition. But between these two extremes of private industry and complete nationalisation there are, I submit, great possibilities in the direction of *State and private partnership*, especially as regards all undertakings of a public service character. It is altogether thinkable that such a system—if applied, *e.g.*, to the railways and canals of this country so as to afford the necessary degree of Government control and direction exercised from the *inside* through Government representatives on the boards of directors, combined with the advantages of private initiative and business administration—would yield better and more co-ordinated results as well as greater economy and efficiency than have hitherto been achieved, either through complete private ownership, as in the case of the railways and canals, or through complete nationalisation, as in the case of the telephone service.

The basic problem in Germany is the same as in this country or in any other industrial nation. Nationalisation enables an industry or undertaking to be conducted in such a manner

as to promote the national welfare. It can be co-ordinated and linked up with other undertakings; the kind of injurious competition that means working at cross purposes can be eliminated, and unity and harmony of control in the national interests can be secured. But, on the other hand, the absence of private initiative and of the motives of personal profit, which are the ordinary incidents of ownership and management, have a strong and invariable tendency to turn the business into a Civil Service department, to force business principles into the background and to bring Civil Service rules into the foreground. The undertaking ceases to be a business and becomes Civil Service.

Private initiative, on the other hand, focuses its attention too much on the earning of a dividend. If a canal competes with a railway, kill the canal because that will increase dividends. The interests of the railway company are proximate and urgent; the interests of the State are too remote to be allowed for sentimental reasons to interfere with the prime interests of the railway. The result may be altogether advantageous for the railway but equally detrimental to the public interest in transport as a means of furthering the nation's commerce and industry as a whole.

How different would be the position if the Government itself were a shareholder both in the railway and in the canal and duly represented on the respective boards of directors. Under such a system all the undoubted benefits and business efficiency of private ownership and initiative for the legitimate purposes of gain could be preserved, and at the same time as effectively brought into line with the national interests, as if the undertaking were nationalised.

This idea of partnership of the State with the individual has made considerable progress in Germany. Several years ago the German Finance Minister von Miquel attempted to secure the controlling interest in the "Hibernia" coal mines. According to the press accounts, as I remember them, he did succeed in purchasing something over 40 per cent. of the shares, and so far as my information goes the German State to this day has continued to conduct this particular mining undertaking in partnership with the private shareholders of that concern.

Again, the Standard Oil Company acquired not long ago a valuable concession in China, and entered into partnership with the Chinese Government for its exploitation, China receiving for the concession a one-third interest, the Standard Oil Company furnishing the capital and equipment and undertaking the management in consideration of the remaining two-thirds interest.

There are sound reasons, both of a legal and business nature, to justify the participation of the State in large private enterprises on the basis of State and private partnership. As is well known, the introduction of corporate forms of industry and commerce has resulted in substituting the "limited company" for the individual employer. The old-fashioned and friendly relationship between master and servant has developed into the hostile relationship between capital and labour, very largely because a limited company is not a human being but an "artificial person," which, in the words of a famous English judge, "possesses neither soul to damn nor body to kick." Shareholders have taken the place of the master, and *hands* considered as units of labour have taken the place of the apprentice. To make matters worse, a process of insulation has taken place, destroying the immediate human contact between shareholder and labourer; and boards of directors, instead of restoring human sympathetic contact, have all too frequently proved to be non-conductors, and therefore barriers to mutual goodwill.

Something must be done to restore human contact between capital and labour. For the time being the war has furnished us all with that common mutual and uniting impulse, with the result that capital and labour are in the main working in harmony and achieving most remarkable results. My suggestion is that the principle of State and private partnership will tend to restore the connection between capital and labour after the prevailing patriotic impulse has spent itself, and that the State is entitled to an interest in large corporate undertakings, and to a seat on the board of directors, as a consideration for the value given by the State in the shape of the charter or corporate rights and franchises granted to such undertakings and upon which their success in large measure depends.

The State that grants a charter to an undertaking, or permits and enables it to become incorporated under a general law, has a right to demand and receive such a share, at least in the control, as will prevent the danger of those rights and franchises from being used in a manner inimical or detrimental to the public welfare and inequitable to the army of British workers.

V.—Banking and Post-cheque System.

One of the most interesting of the more recent examples of the spirit of progress in German methods is that afforded by the institution of the so-called "post-cheque system." A number of causes have combined to call this system into being. One of the main causes is undoubtedly to be found in the condition of the German banking system. Much has been written about German banks and banking; some are never weary of praising the great efficiency of the German system; others again are not slow in detecting numerous flaws and deficienc es. Both are, in a sense, right. The German banking system is undoubtedly efficient in some directions, and equally deficient in others. Perhaps I may best explain what I mean by saying that it is almost the opposite of the American system. German and American writers and representatives of business have frequently indulged in mutual criticism of their respective banking systems, some of which criticism has been of a decidedly drastic character.

The Germans maintain that the Americans do not understand the theory and philosophy of banking, and that they do not even have a national bank. They say that the only two attempts on record made by the United States to establish a real national bank failed partly because of ignorance of banking science and partly because of the political corruption inherent in American politics.

The Americans, on the other hand, were not slow to point out that, as far as the German banks—considered as institutions of use and convenience to the business world—are concerned, they must be considered as in every way primitive and deficient. The book-keeping is involved and cumbrous; the amount of time which customers are forced to consume in connection with such simple operations as making a deposit is a waste of time and a nuisance; bank clerks and other employees are slow and inexact, have no conception of the value of time, are slovenly, lacking in promptness, and very frequently lacking in business courtesy. The arrangement and office equipment are antiquated, and they are years behind the American practice in the use of calculating machines and other mechanical aids to banking operations. Finally, and most serious of all, the German banks were a hundred years behind the English-speaking world in the use of the cheque as a mode of payment.

On this point in particular the American was able to get back at the German with a good strong counter-stroke touching the theory and philosophy of the cheque, which still seem to be in their infancy in the Fatherland. Whether this backward state of things as regards the use of the cheque was due primarily to the bank or to the defective conditions of the law, is a point of some interest. It is true that the prevailing legal provisions governing cheques are totally inadequate to permit the use of such a cheque as would give the public the same or equivalent guarantees of safety as are afforded under the British or American system. All cheques must be made payable to bearer; cheques payable to order do not exist and are contrary to law. There is, therefore, no need of endorsement, and such cheques, even if endorsed payable to order, are nevertheless treated as payable to bearer. The endorsement is practically without value. For this reason, the giving of a cheque in payment of a debt does not in itself constitute evidence of payment of the debt, and there is no endorsement by the payee to operate as a receipt.

It is, and must remain, one of the interesting paradoxes of German progress that such an abnormally primitive state of things could continue to exist in a community so highly developed in the direction of commercial and industrial efficiency. Eminent Germans themselves have not been slow to agitate for a reform, and during the few years preceding his death, Geheimrath Koch, of the Imperial Bank, made it the main object of his life to press the Government for a reform of the law of cheque, in order that its use might be popularised with safety both for the convenience of the business world and in order to accustom the rank and file of the German people to deal with banks and to entrust their money to the banks, rather than to hoard it up in the family strong box or feather bed.

Slowly but surely the reform movement has set in. The Government, the Chambers of Commerce, professors of economics, the banks, merchants and exporters, and, indeed, the general business public, were gradually becoming alive to the deficiencies of the existing system, and to the necessity for placing the German cheque upon the same basis of usefulness and security as the English or American cheque.

The President of the Society of Comparative Jurisprudence was also interested in the question, and, since he was himself the author of a project for the establishment of a uniform world law of bills, notes and cheques, he devoted his special attention to the necessity of directing the German reform of the cheque in such

directions as would bring it as far as possible into harmony with those principles and legal rules governing the cheque and its use which had, through experience in other countries, been proved to be of sterling value.

The *Post-cheque System* was, in the main, the outgrowth of the agitation in favour of the greater use of the cheque as a medium of payment, but it was also due in part to the evolution of the postal C.O.D. system and the "Geldbriefträger" (lit. "money letter carrier"). Under that system, which could either be employed in connection with the parcels post or independently, it was possible for anyone in any part of the Empire to constitute the General Post Office his *collecting agent* for the presentation of bills and receipts and the collection of the amounts due in any other part of the Empire. What occurred in former years was this: The money letter carrier, on presenting the C.O.D. order usually received payment in bills and specie, and placed the same in his leathern wallet for delivery to the branch post-office to which he was attached. In due course the post-office in which the order originated sent its money letter carrier with an equivalent amount in bills and specie for payment to the creditor.

The same thing occurred when it was desired to remit money by post-office order to a payee in some other part of the country. It is thus seen that the business of remitting moneys as conducted by the German post consisted of the carrying out of (1) orders to *remit*, and (2) orders to *collect*.

In the course of the rapid development of commerce and industry it was becoming more and more apparent that the business community regarded this receiving and paying out of bills and specie as wasteful, inefficient, and irksome—wasteful because it was necessary to keep money on hand instead of drawing daily interest on deposit account in the banks; inefficient and irksome because it was a roundabout method of doing what could be more expeditiously accomplished through the banks. On numerous occasions I have myself received remittances from various outlying parts of the Empire, which were handed to me in bills and specie too late for deposit in a bank on the day of receipt; I have also frequently received larger amounts, several thousands of Marks, and therefore beyond the postal order limit, in the shape of registered letters containing bills, coin and even postage stamps for the fractional amounts.

The waste of time and labour involved in having a money letter carrier paying out sums in this manner, which the receiver immediately sent by another messenger for deposit in his own bank, was so obvious that the postal authorities themselves began to consider ways and means of shortcutting these processes. If the banks of the Empire could remit and collect moneys for their patrons by the use of cheques or orders, and could avoid the actual handling of the amounts involved by the simple expedient of passing such cheques and orders through the clearing department of the Imperial Bank for debit or credit of their patrons accounts, why could not the Post Office do the same? The business public was already accustomed to this modern process, and the banks were deriving profit from the increasing volume of deposit accounts; why should not the rank and file of German subjects also be brought into line both for their own convenience as well as for the resultant benefit of the Postal Treasury?

A scheme was therefore carefully prepared which soon became law, and which provided that any person on depositing £5 could open a post-cheque account, and receive a book of cheque forms with his name or firm printed thereon, and with the serial number of his account. In order to make any number of remittances it was only necessary to pay the covering amount, if not already here, into his post-cheque account and to fill in the names of the payees, whereupon the process of remittance and distribution would automatically be carried out by the post. If the payee had no post-cheque account, the amount would be paid out through the medium of the money letter carrier as formerly; but if he had an account the amount would be credited thereto. The money letter carriers were instructed to explain to the payees that they could save the delivery fee by opening a post-cheque account; these letter carriers thus became an army of propagandists to educate the people to the new idea.

Statements of account were sent regularly by the post to the respective account holders, with a form on which they could direct that such portion of the moneys to their credit, which they might not require as a working margin, should be paid into their respective banks to the credit of their accounts, and I believe—although I am not certain on this point—that this process was accomplished through the medium of the clearing department of the Imperial Bank.

The number of such post-cheque accounts increased very rapidly. The institution did indeed fill a "long felt want." There must at this

time be several millions of such account holders, and, since every million accounts means at least £5,000,000 of deposits without interest—in practice it would be much more—the benefit to the State is very considerable, because on the one hand it has the constant use of that money without interest, while on the other a very material reduction in the labour and number of the money letter carriers, who were more highly paid than the ordinary postmen, was made possible.

Under this system the German Post Office has developed into an enormous Imperial Petty Bank, with a larger number of highly organised branches and skilled personnel than is possessed by all the other banks put together. And this has been accomplished without creating hostility and opposition on their part, because it has relieved them of the comparatively unremunerative business of dealing with small amounts, and has freed them to concentrate their attention on the larger banking business of the German commercial and industrial community.

VI.—Science and Language.

One phase of German development which was very noticeable was the prevalent belief that they had in fact attained to what I may call the "hegemony of science"—that they had become the great source of the world's most advanced scientific thought, and, as a corollary thereto, that the German language had become the standard medium of scientific expression. Henceforth the source and idiom of all true science would bear the Teutonic hall-mark. The claims frequently put forth on behalf of the English language as being a universal world tongue were dismissed as devoid of substantial foundation, and due at most to fortuitous causes of a superficial nature. How, it was sometimes asked, could any language aspire to become a world language when the fact of its widely extended use was due merely to geographical considerations and British ignorance of foreign tongues? According to the German view, the English tongue had become merely a sort of a *world jargon* mainly on account of Britain's geographical extension, commerce, shipping, and the like, taken in conjunction with the Briton's proverbial neglect or disdain of foreign tongues. Its extensive use was not due to any special virtue inherent in the language itself, for it was inexact and unscientific; it had far too many words signifying the same thing, and far too few words expressing scientific differentiation.

The growth of language, it was said, was conditioned upon the growth of thought, and, since scientific thought in Germany had outstripped scientific thought in the English-speaking world and elsewhere, the German language had become a world language of a higher type, based not upon geographical but intellectual dominion. All those who would drink deeply at the source of science must, perforce, do so through the German idiom as the "key language to the world's science." If any one were in doubt about the matter he had only to glance at the enormous output of German scientific books and periodicals in comparison with the output of all other countries together to convince himself of the reality of this fact. I am not qualified to speak on this matter as regards other branches of science, but there are a few facts touching the relation of the German language to legal science to which I may profitably refer.

As preliminary thereto, just a few words on the development of German law. Prior to the founding of the present Empire there existed in the German States a condition of legal confusion. The process of unification and codification had set in with the establishment of the Empire, and achieved its greatest success in the preparation and adoption of the new Civil Code, which went into force throughout the whole Empire on the first of January, 1900. It has been pronounced by those who ought to know to be a worthy successor of the great Napoleonic Codes of a century ago. It has certainly justified its existence, and has served both to popularise legal principles and to increase the practice of order and exactness in the legal relations of the people.

But the scientific appetite of the German jurists for systematising and codifying law was still not satisfied, and craved fresh food from foreign fields. What more inviting field could there be than that afforded by the world-wide commerce and shipping of the Fatherland? Why not collect, annotate, and publish the Commercial Laws of the World? And what other nation was so well fitted as Germany to undertake that work of science? England, now in decline, had not even in the zenith of her commercial and industrial greatness accomplished such a task, and at the present time she was—

"Zu geistig faul um es zu unternehmen; zu oberflächlich um es wissenschaftlich durchzuführen."

[Too mentally indolent to undertake it;

too superficial to accomplish it scientifically.] Therefore, as in the art of war, so also in the arts of peace—"Germans to the front."

Therefore, six or seven years ago, this excellent idea was taken up in earnest. With the patronage and help of various official bodies—professors, judges, lawyers, and others—it was proposed to compile and issue these laws in a number of volumes embodying the polyglot principle. The commercial laws of each country were to be reproduced in the original text and language, and also in the German language on the opposite page. By this means the German language became the common or *key language* in which could be found the commercial laws of all countries. By adopting the method of first compiling and editing the commercial laws of each country in the original language and text of that country, the German publishing house was able to avail itself of the services of the leading professors and lawyers of each country, and when they had completed their work it only remained to prepare the necessary translation into the German language in order to make that language the key language of all trading communities as far as their laws were concerned.

This may truly be said to be a monumental work, comprising some thirty large volumes. The French manufacturer or merchant dealing with Russia can ascertain the laws of Russia by reference to the German version as the key. The Russian desiring to do business with the outside world can find the commercial laws of any country with which he desires to deal both in the original text and in the German idiom.

The value of such a work was evident to all. It was widely sold in Germany, and also in fairly large numbers in various other countries, and, of course, the libraries, chambers of commerce, commercial and industrial associations, and large numbers of private business concerns manufacturing for and exporting to foreign markets were glad to purchase it as a work of reference. In the preparatory task of peacefully penetrating other nations this work constituted a valuable weapon.

Another German compilation which falls under this category is the Patent Laws of the World, compiled and edited by Professor Joseph Kohler, of Berlin. As is well known, the Germans, wherever possible, apply the principle of *quid pro quo*, or reciprocity and retaliation, in their codes and statutes, and in their treaties and arrangements with foreign countries. According to their conception of the principles of Patent Law, the grant of a patent is the grant of a valuable State monopoly. In return for the conferring of such an advantage upon the inventor, he is required to work his patent within the Empire, in order that some part of the benefits and advantages to accrue from the exploiting of the invention may accrue to the German State, in the shape of employment afforded to its subjects and opportunities of investment given to German capital, etc. In default of its working the State may withdraw the monopoly.

It can be seen at a glance that the German inventor, and the capitalist behind him, had the liveliest possible interest in securing due patent protection at home and abroad, and on the most favourable terms. Hence the value of a convenient and fairly exhaustive compilation of the patent laws of other countries in order to enable the largest possible measure of State protection to be secured as a valuable and essential condition for the successful exploitation of his invention in the markets of the world.

Finally there remained the task of rendering the civil laws and codes of the world into German. This project was taken up some years ago by the Berlin Society for Comparative Jurisprudence. Its general intention was to produce a series of works modelled after the pattern of the German Civil Code of 1900. Owing to the progress of codification it was not difficult to secure and translate the civil laws of such countries as France, Italy, the South American Republics, etc., in which the Napoleonic codes or modifications thereof had long been in use.

But in the case of the English-speaking nations the matter was different. It was felt that the English Civil Law (which also included the principles of commercial law) constituted, so to speak, a "key" to the legal systems of all the English-speaking communities of the old and the new world.

But as long ago as 1866 it had been computed that the English judicial decisions occupied more than thirteen hundred volumes and a hundred thousand cases, and the last half century had materially increased that figure. The work of reducing this vast mass of decisions, the statutory enactments and the body of equity law to a systematised and logical series of rules and principles like that of the new German Civil Code appeared to be too great an undertaking for any of the available German professors. Nevertheless, it was imperative that the work should be done, and if the British would persist

in neglecting to codify their law somebody else must do it, because the Germans required it for their own scientific and practical purposes.

An opportunity presented itself, however, to the President of the Berlin Society to interest an English professor in the work, and Professor Jenks was induced to undertake the task and to secure the co-operation of his friends in carrying it through. The work has just been completed, and constitutes an admirable exposition of the principles of English Civil and Commercial Law, formulated in the shape of a Code on the lines of the German Civil Code, and containing some 2,000 odd sections. It is a work possessing both scientific and practical value. It is, so far as I know, the only work from which the foreigner accustomed to codes can get an intelligible idea of English law. If it had been completed at the time that the Japanese were preparing to reform their laws there is every reason to believe that they would have taken it as a model, for it is known that they greatly admired British Courts and administration of justice, but found the law itself too intangible to grasp and take home with them as a model. They therefore took the new German Code instead as their model.

The point I wish to emphasise is that the German regarded this as another example of British lack of initiative and progress. In place of the patchwork of existing statutes and decisions, which no foreigner and but few Britons can intelligently understand, the Germans had stepped in and caused an excellent draft of English law in code form to be prepared, which they could henceforth use to their own great advantage in their dealings with this country for the purpose of peaceful penetration. The German edition of the work is replete with annotations, explanations, historical data, and the various glosses so characteristic of German scientific works in which every nook and corner of the subject is explored.

I have no hesitation in saying that any intelligent German, by a careful study of the work, can make himself more familiar with English law in the same space of time than would be possible for the average Briton to secure by consulting the ordinary legal literature of this country.

VII.—Political.

There are some features of the so-called German constitution which may be referred to with advantage. The Germans, apart from the Social Democrats, imagine that they have a constitutionally responsible form of Government. It would be a waste of words to attempt to demonstrate that this is not so. It is true that they have something which bears an outward semblance to a constitutional form of government, but when analysed it will be found to be merely a form of absolutism masquerading in constitutional garments.

In the United Kingdom and the self-governing British Colonies, and in the other democracies of the world, sovereignty—in the words of Tennyson—is "broad based upon the people's will." The people collectively constitute the broad foundation, then come the people's representatives in Parliament, higher still the members of the Cabinet, who are likewise members of Parliament by virtue of popular election, then the Prime Minister, and finally the Sovereign—a triangle based upon the people, and with the Sovereign at the apex. This picture, with but slight variations, applies alike to this limited monarchy, and all its self-governing dominions, and to the great Republics like the United States and France, with the substitution of an elective instead of an hereditary head. In Germany, there is indeed a Parliament containing the people's representatives, and hence "broad based upon the people's will"—but there the constitutional edifice stops. High above people and Parliament is a Kaiser, by the grace of God, with Ministers chosen by the grace of the Kaiser.

The Kaiser and his Ministers thus constitute a kind of Cabinet of super-Germans, who from their lofty position graciously descend from the German political heaven until they come into touch with the people's representatives on those occasions on which it is necessary to secure the latter's sanction to Governmental measures.

This super-Cabinet is above the Reichstag, but not of it, and the fact that Chancellor and Ministers from time to time take their places upon the tribune and expound their measures and policies, so far as, in their opinion, the people's representatives are entitled to an explanation, does not alter the basic facts of the case. There is no doubt whatever that the Kaiser and his Ministers regard themselves as being primarily charged with the duty and privilege of formulating domestic and foreign policy, and that in so doing they are exercising creative and originating functions of government, and merely go to the people's representatives to secure their approval and obtain the means. There is, therefore, no necessary connection

between the Cabinet and the majority of the popular chamber.

Since, therefore, there is no one party or group of parties in the Reichstag constitutionally entitled or otherwise empowered to form a Cabinet, and dependent for its existence upon its ability to command a majority of the popular chamber, it follows that there is not, and cannot be, a two-party system with a majority charged with and responsible for the business of governing, and a minority exercising the functions of criticism. Wherever in any State the majority is charged with the business of Cabinet building and governing, there is always a dominant tendency at work forcing the popular representatives according to their various political ideals and objects, into alliance with the majority or minority group. Although so-called third parties may appear, and even maintain themselves for a time, they become gradually absorbed into the one or the other group in the course of those processes of reformation constantly going on.

The opposite is true of the German Reichstag. The absence of that compelling necessity to form Cabinets and undertake the constructive work of governing liberates all parties to go their devious ways, and gives unrestrained play to the tendency of segregation which has been so observable in the history of the German peoples. That explains why there are so many different parties or fractions—anywhere from ten to sixteen—in the popular chamber, each with its party organisation and leader. Under these circumstances, nothing could be more grotesque than the exaggerated importance attributed to this or that party by most British and American journalists.

How does the super-Cabinet manipulate these various parties? It does so through the institution of the "Block," as it has come to be known in recent years, especially under the *régime* of the ex-Chancellor von Bülow, although the main features of the system were long practised by Bismarck. Far too little attention has been paid by British writers and students to the working of this system, and the majority of foreign journalists in Germany have not, I think, sufficiently and clearly interpreted to their readers the inner meaning and significance of "block policy."

Neutralisation and *compromise*. Parties were poisonous to Bismarck; he therefore treated them as poisons, figuratively speaking, and contrived to pit them against each other so that one poison would become the antidote of the other and neutralise the action or influence of both. Again, if, *e.g.*, the Conservatives desired a certain measure which was opposed by the Social Democrats, the Chancellor could say to the Conservatives, "Modify your opposition to the Social Democrats or your measure will be defeated"; and likewise to the Social Democrats, "Withdraw some of your opposition to the Conservatives or you will not get your measure through," and thus, by forcing opposing parties to compromise their more extreme demands, the hands of the Government were freed to deal with those phases of the respective bills which the Government most desired, and upon which contending parties could be forced to a compromise on pain of receiving nothing at all. Not only individual parties or fractions, but groups of parties or "blocks," are thus pitted against each other, neutralised, and forced into compromise, in order to enable the Government to push through those legislative measures which it regards as necessary and beneficial.

With the exception of the Social Democrats, the German parties have in the main been content with this form of what they call "strong Cabinet Government modified by Parliamentary action."

Many thinking Germans with whom I have conversed have openly admitted that this system is, in fact, not democratic but eminently suited to the German temperament and State. They maintained that, under the British system, majority and minority were in effect two "blocks," so intent upon butting their heads together and thus neutralising themselves that they frequently accomplished little or nothing, because there was not sufficient independence and reserve power left in the party Cabinet to push through those measures which, whether in the interests of this or that party, were certainly in the nation's interests considered as a whole. Many valuable measures had thus been nipped in the bud, while many other desirable measures had not been formulated and introduced at all. In the car of State, the majority was the motor and the minority was the brake, and they were ofttimes so evenly balanced that the car moved neither forwards nor backwards, but stood still in its tracks. Therefore, there must exist above parties some strong propelling and governing force keeping the interests of the nation, as a whole, constantly in view as the true objective and striving to obtain it, not indeed regardless of popular opinion, but with its aid if its many tongues

could be brought to agree, without its aid where they lost themselves in endless contentions.

This is, in effect, precisely what the German Chancellor in his latest speech (*vide Westminster Gazette*, February 28th) means when, in referring to the immense intellectual, economic and social tasks to be faced after the war, he says, "We can only solve them if our entire strength . . . continues to work in peace time, if paths are created for this strength in which it can freely and joyfully continue to work. This cannot be regulated from the party standpoint, but demands internal strength in the State"—which, in plain English, means that it must continue to be the high prerogative of the Kaiser and Cabinet to lay out the racecourse, and the duty of the people, without question or parley, to do the running.

I have referred to this phase of the German political system because I think it has a vital bearing upon the extraordinary scientific, industrial, and commercial progress of the Empire, and serves to explain why, notwithstanding the multiplicity of parties and the greater multiplicity of conflicting opinions, it has been found possible to put measure after measure upon the statute book, to expand the army, build up the navy, to co-ordinate and develop commerce and industry, and indeed to impart to the whole fabric of the nation's activities a sense of direction and purpose which, so far as material progress is concerned, has challenged the admiration of the world.

Its utter moral failure, however, is being writ large upon the battlefields of Europe.

DISCUSSION.

The Chairman (Mr. Edward Dent), in opening the discussion, said that a great deal had been heard about peaceful penetration by Germany, but he thought a great deal of that peaceful penetration was meant to develop into warlike domination. It had been very interesting to hear what the author said about the support given by the German Government to the various German business houses abroad, and he believed that in many cases the business house was simply a spying agency for the Government, as were also many German missionaries, who acted in combination with German agents in the colonies. He thought the Governments of this country and the colonies were now awake to that fact, and that in most colonies the German missionaries had been interned. Germans had often been considered rather unsuccessful in managing their own colonies, but successful in the colonies of other countries. That idea, however, had now given place to the belief that Germans simply went to other people's colonies to find out what they could of the country, and then to communicate the information to their Government at home. At the time when the war broke out in 1914, the British Association were holding their meeting in Australia, and he believed it was afterwards discovered that some of the German professors who attended that meeting went home with very useful military maps of Australia, which showed that the peaceful penetration of Germany was not always disinterested.

Mr. James Swinburne, F.R.S., said that Mr. Vickery's paper was a most important and interesting work, which ought to be read very carefully when it was published in full. With regard to the point that the Germans simply instructed instead of training character, quite recently a man who knew the Japanese very well told him that he had been discussing the matter with a Japanese who had been in Germany for some time and then came to England, and who thought that, although German education was much more complete and satisfactory in many ways, yet English education produced character while the German system merely produced people containing a certain amount of information. Again, a German book on science would be full of information, and would contain everything that had been done or said or written with regard to the subject with which the book dealt, but there would be no sense of proportion about the book. Ten pages might be devoted to an exceedingly important subject, and twenty pages to one that was of no importance at all. Further, in a German treatise not of the highest standard there might be found all the theories on the subject, although those theories were mutually exclusive. Many people thought that the Germans were an inventive people, but that was not so; practically the only inventions that came from Germany being in organic chemistry. Their method of working almost precluded them from inventing anything. In the early eighties, for instance, America was very active in developing electrical plant and machinery; England was equally active, but was hindered by legislation from doing much in the way of manufacturing. When he went over a particular works in Germany, about the year 1890, he found that they had simply taken English and American practices and combined them, selecting the best of each, and in that way they had developed a huge business. With regard to the author's suggestion that some kind of partnership might be made between the Government and private owners, it seemed to him that the powers of the Government should always be kept down as much as possible. In any Government-controlled business the chief places were occupied by politicians and their friends. If any of those present had had much to do with Government offices they would know that the heads of the different departments would never

take any responsibility. Such things as the Post Office and telephone service might be run by the Government, because they were supposed to be too big to be managed by private individuals; but in other countries they were privately owned, and the financial result of the English Government taking over the telephones was well known. He did not think the combination of the Government with private owners would tend to sweeten the relations between capital and labour, and the Government generally did not get on very well with its labour. With regard to the post-cheque system in Germany, he did not know whether it would be worth while to urge the adoption of that system in England. Many English banks seemed to dislike dealing with small cheques; but he thought if the Government were to take up the matter it would prove more expensive to the community than if it was done through the banks. The Birkbeck Bank had been very convenient in that respect, because, as it charged 1½*d.* instead of 1*d.* for its cheques, it liked people to send small cheques. The postal order system was also useful for sending small sums of money.

MR. F. W. MOORE thought the author had traced the evolution of the German as he was to-day. A man was necessarily the outcome of the conditions and environment in which he was placed, and it seemed to him that the control that had been exercised over the German nation for so many years by the governing class led to the result that the individual necessarily lost initiative and independence of thought. The Germans were the most obedient and almost servile people, in so far as their own Government was concerned, that could be found in any European country at the present time, and there was less independence of thought amongst the Germans in general than amongst any other Continental nation. They liked to be controlled, and could be made to give particulars as to their income, etc., without any trouble whatever, having been trained by a long process of education and police control. He wished the author had touched a little more emphatically on German police control, which was one of the most complete organisations that had ever been devised in any country. If the Government was going to control the nation for the purpose of exploitation it would introduce co-operation, but in doing that it would cause loss of individuality, loss of humanity, and ultimately produce a lower-grade human being. According to all accounts, Germans were capable of the utmost brutality. It appeared that a German soldier was prepared to commit any crime and pass on the responsibility to his officer; that was the outcome of their system of drill and discipline. With regard to Government support for private enterprise, he thought the British Government had a good deal to learn in matters of business before they took over any privately-owned enterprises. In conclusion, he desired to express his appreciation of Mr. Vickery's paper, which he had listened to with great interest.

MR. OCTAVIUS C. BEALE wished to add his testimony to the great value of the paper. He was deeply interested in the subject, because he had taken a great deal of trouble to study the German psychology and also German methods of business. He had recently read a book bearing on the subject entitled "Les Méthodes Allemandes d'Expansion Economique," by Henri Hauser, which he would recommend those present to procure, as they would find it of great value. He remembered in 1885 hearing a German Australian merchant say to a German manufacturer, "We are the Chinamen of Europe," meaning that they were copyists; and it was perfectly true that all the leading inventions were of British origin. Germans had learnt all they knew about railways, electricity, and metallurgy from Great Britain, and then had developed and exploited those discoveries. English people had a power of specialisation which the Germans did not possess, and therefore the Germans did not attain any very great success in commerce in our Overseas Dominions. In Canada, Australia, and South Africa the German farmer would cultivate many things at the same time, whereas the English farmer would turn his attention to one thing in particular and attain perfection in it, so that he easily surpassed the German. In many ways Germany was superior to Great Britain in organisation. As a Royal Commissioner he had taken part in investigating the subject of quack medicines, in regard to which this country enjoyed a notoriety unapproached by any other, whereas in Germany such medicines were under absolute control. Again, with regard to unfair competition, there was no law in this country to protect the honest trader against the dishonest, such as there was in Germany. With regard to the Government of Germany, the point was often overlooked that, if it had not been for the war, the Social Democratic movement might have capsized the whole of the wonderful institutions in Germany. They had already arrived at a representation of 110 in an Assembly of 370, and might have revolutionised the country.

MR. W. S. HOLDER said that Germany had placed her Consuls all over the civilised world, not only to represent German interests, but also at times to represent English interests. That had been, and still was, a disgrace to England as a nation. From time to time the Commercial Travellers' Association, to which he belonged, had entreated the Government to appoint only Englishmen as English Consuls. In Buenos Aires there was a large British Consulate and also a German one, and the difference between the two was so astounding and so alarming that one was led to think that the former was for pleasure and the latter for business. A certain buyer

of goods once went to the British Consulate, where he was treated very politely and given the addresses of between twenty and thirty manufacturers in Birmingham and Wolverhampton who made the class of goods he wanted. He wrote to those manufacturers and received from them, as usual, price lists of their goods, written in English and quoting the prices in English money. Disgusted at that, he went to the German Consul and was shown into a room containing a sample of every kind of article that the Germans could make or procure. He was asked what particular article he wanted, and was taken immediately to that department, the Assistant-Consul who showed him round telling him in Spanish exactly what the article he required would cost him in Buenos Aires, including carriage, duty, etc. Naturally his order went to Germany. There were many German methods that it would not be well to copy, but some of their business methods might well be adopted by this country.

Mr. A. J. David, K.C., agreed with what previous speakers had said in regard to organisation in Germany and the lessons that England might learn from that country. He wished to emphasise the need for the development of technical education in this country, with regard to which Germany had had a great advantage over England for many years past. People in England would not take the trouble to treat low-grade and refractory ores, although that might often be done with advantage. Ore imported into this country from Spain had been discharged in the neighbourhood of Whitehaven, refused because there was a quantity of refractory ore amongst it, re-shipped, taken to Germany, and then treated there. The Germans made it worth while for men to study science, whereas in this country no encouragement was given to research. He hoped one lesson the war would teach us would be to give up living upon our prestige, to take advantage of the opportunities that were given to us, and not to allow Germany to step in front of us in all the Neutral markets of the world.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

KELP INDUSTRY IN BRITISH COLUMBIA.

For several years the question of utilising the supply of raw material to be found in the kelp beds along the British Columbia coast, for the manufacture of potash and other products, has occupied the attention of Vancouver capitalists, and, according to a report by the United States Consul-General at Vancouver, processes have been perfected in recent years by which it is claimed that potash can be produced from kelp at a cost sufficiently low to compete in the American market with potash salts imported from Germany.

A company was organised in 1915, and a plant established at Sydney, British Columbia, for the production of potash and algin. This company is now utilising from thirty to forty tons of raw kelp daily in the manufacture of fertiliser. The product is a fine, dry, but heavy powder. Plans are being made to enlarge the plant and instal special machinery for the extraction of other materials from kelp.

It is believed by the promoters of the industry in British Columbia that the manufacture of iodine and potash, without the production of by-products, would not prove very profitable in normal times, but the increase in the price, especially of potash, on account of the war, will enable the British Columbia Company to include these and other by-products in the output of the factory at Sydney.

Algin, which will be made one of the specialities of the local plant, is said to possess a viscosity many times greater than that of starch or gum arabic. The chief use of algin is for the sizing of fabrics, the effect being to give the material treated the appearance of waterproof sheeting, but leaving it more elastic than when treated by other customary waterproofing materials.

The value of potash imported into Canada annually is about £200,000. It is estimated that the kelp beds on the coast of British Columbia contain sufficient material to manufacture potash, not only for the local market, but for export also.

An Act relating to the licensing of kelp-reduction works, designed especially to encourage the development of the industry and for the protection of persons or companies desiring to engage in the business, was passed by the 1915 session of the Provincial Legislature. The industry is under the jurisdiction of the Minister of Fisheries. A licence protects the operation of any reduction factory for an area extending fifty miles along the coast.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Essential Trades.—External influences command far more attention than any internal developments, and textile industry has, indeed, ceased to develop, save as it may be allowed by the hand of authority. From being a business in which one was free to do as well as one was able, it has gravitated into one in which the manufacturer is free to do as he is told. Progress along the narrowing path is marked by events like the Government purchase of all unsold stocks of raw jute and the discovery that wool cannot be got to execute private orders. Cotton is still a free market, subject only to some safeguards against speculative dealing, but cotton manufacture is ominously absent from Mr. Neville Chamberlain's first list of trades and

occupations of primary importance. The list may conceivably be extended, but the omission is eloquent. Not many men expected to see the day when the greatest textile industry could be written down as of secondary importance. There may, however, be cause of cheerfulness in the fact that raw cotton is excepted from the list of imports marked out for reduction or prohibition. Comparisons are apt to be odious, but a glance may be permitted at the list of primarily important textile trades. "Woollen and worsted manufacture and finishing" under existing conditions excludes nearly all else than Government and export work. There is an imperative need to husband the available resources of wool, but the measures taken to that end have not yet commended themselves to everybody. Of woven wool goods and hosiery, which come next upon the list, over £100,000,000 worth have been purchased by the War Office, and from this eminence the descent to other articles regarded as of first importance is a steep one. Rope and twine figure next, and provoke surprise at the omission of sandbags and some vitally important linen goods. These missing articles are presumably covered by the omnibus clause which includes all munition trades not directly specified. In that case there is a question why silk shalloons are not deemed to be protected by the same general provision, for they are munitions or nothing. These coarse, canvas-like silk cloths are manufactured from silk noils, a by-product of the dressing of waste silk, and are used as cordite containers. Transmission belting is scheduled and, except in the comparatively rare cases where it is made of hair or strong wool, this belting is a cotton duck, painted or coated with balata. The waterproofing of military fabrics is an expressly protected trade and a fairly important one in these times, although not more so than some which obtain no mention.

Restricted Imports.—Some of the textile articles enumerated in the Royal Proclamation have figured in earlier lists of prohibited imports. Cotton hosiery, for which this market has been wont to rely upon foreign sources, is one example. Germany was the main furnisher before the war, since when American and Japanese sendings have become considerable. The large sale of American cotton and artificial silk stockings provoked open dissatisfaction in the Midland centres of industry, but the embargo placed upon imports was postponed and then withdrawn. The pressure of Japanese interests was the ostensibly effective agent, and renewed objections may be looked for from Japanese manufacturers who have installed special machines to make garments in European sizes. The prohibitions upon raw jute, linen, linen yarn and goods are related obviously to the Government desire to control the total supply, and are to be regarded in another light than the restrictions upon superfluities. Silk manufactures, embroideries, cotton lace, gloves, incandescent gas mantles, and unwaterproofed apparel are not luxurious in equal degree, and it is possible that utility will be one consideration taken into account in the issue of licences. There are silks which justify their employment as being actually the most economical articles to use for the purpose, and the origins of the silk goods imported at the present—French, Swiss, Italian, and Japanese—promise some complicating circumstances.

Trade Petitions.—The system of trade licensing, although accepted as a necessity of the situation, has not made itself popular, and a clamour that has arisen for more licences implies no affection for the system for its own sake. A number of Manchester shipping merchants, aggrieved by the delays caused to export orders by the attention shown to home orders, have advocated a new system of priority. They would have exporters licensed, and issue to them labels which would ensure priority for their goods next after Government contracts. The object is defensible enough, but the idea of penalising the rival home traders has not commended itself to the Manchester Chamber of Commerce or to the general sense of fairness. A whole series of manifestoes proposing schemes for the exclusive benefit of export trading has been published, and can hardly be perused without recalling the sectional trade petitions which were so much more common two or three centuries ago. It may, of course, be that the plaintive representations of Manchester exporters to the several departments of State will serve the historian in the future as evidence of industrial conditions during the Great War.

Bulrush Fibre.—A succession of loose screws may be noted in an American newspaper account of German success in devising a substitute for imported fibre. The enemy would have done well to introduce a material capable of replacing cotton or jute or wool, and it is merely destructive of credibility to claim for one fibre the ability to replace all three. What is a good substitute for one makes a bad one for the others, and an account equally enthusiastic about the coarse jute and the finest cotton effects to be derived from one and the same source is an account to be distrusted. This vegetable phenomenon is "a plant called typha, a sort of cat-tail, growing in the marshes" to an estimated weight of five or six million tons a season. It is presumably one of the Typhaceæ, prosaically known as a small bulrush or reed maize, bearing a fruit covered with long down. According to the report, 10 tons of material go to 1 ton of fibre, and if the sanguine vaticinations of a Berlin merchant have been realised, Germany is by

now well on the way to independence of America, Egypt, and India for cotton. Typha growing apparently involves no trouble, and experiment has shown that the cost of manufacture is slight; but it must be assumed that harvesting will mean a certain amount of labour. Typha is seemingly more plentiful in the German marshes than in ours. Cotton is not signally cheap in England, but spinners continue to look abroad rather than use the *Eriophorum vaginatum* or cotton grass, which blows in profusion every year on the Pennines, and is doubtless just as poor a substitute as typha.

Scarce Materials.—An official request to be sparing in the use of chlorine for bleaching purposes has been reiterated, and a suggestion has been offered that the home public might content itself with the lower degree of whiteness obtained by simply scouring cottons in alkali. Were that suggestion accepted, bleaching powder would be released for use upon goods for export to peoples who place exaggerated store upon the pure whiteness of their goods. The importance of maintaining unimpaired the surface character of standard British makes of export cotton goods was perhaps better realised three years ago than it is to-day; but the importance remains. There have been hints of a ban upon the use of flour for sizing cotton cloths; but there should be little to fear upon that score if those in power retain their sense of proportion, and weigh against the small saving which could theoretically be effected the great and permanent cost to British trading interests. The small expenditure in starch and gluten is made remunerative in several ways, and were the continuity of the business broken for any considerable length of time trade of a character valuable even in war days would be lost beyond recall. It is natural to talk of substitutes for flour in this connection; but manufacturers employ all the alternatives that there are, and utilise each for its exact worth in giving the particular character demanded by the market.

OBITUARY.

ROBERT P. PORTER.—Mr. Robert P. Porter died on February 28th from injuries received in a driving accident.

He was born at Norwich in 1852, and after being educated at King Edward VI. Grammar School in his native town he proceeded to America, where, in 1872, he joined the staff of the *Chicago Inter-Ocean*. Devoting himself to the special study of tariff and economic questions, he was appointed United States Tariff Commissioner in 1882; shortly afterwards he was employed in the Census Office as an expert in wealth, debt, taxation, and transportation, and subsequently he became Director of the Census. Under the presidency of McKinley, he acted as Special Fiscal and Tariff Commissioner to Cuba and Porto Rico in 1898, and in the following year he successfully undertook the task of inducing General Maximo Gomez to disband the Cuban army.

In the meantime he had been kept busy with journalistic work. He was on the editorial staff of the *New York Tribune* and *Philadelphia Press* from 1884 to 1887, and in the latter year he founded the *New York Press*. In 1904 he joined the staff of the *Times* as first editor of the *Engineering Supplement*, and he was also responsible for many of the special supplements which have been brought out during the last six or seven years.

He was the author of numerous books, including "The West in 1880"; "Breadwinners Abroad," a study of economic conditions in Great Britain and other countries; "Life of William McKinley"; "Industrial Cuba"; "Dangers of Municipal Trading"; "The Full Recognition of Japan"; "The Ten Republics," an economic and industrial work on South America; and at the time of his death he was completing a short history of Japan for the Oxford University Press.

Mr. Porter joined the Royal Society of Arts in 1905, and in the same year he read a paper on "London Electric Railways," for which he received the Society's silver medal.

CAPTAIN ALEXANDER PETER BAILLIE.—Information has been received of the death, on February 26th, of Captain Alexander P. Baillie, who had been a member of the Royal Society of Arts since 1879.

He joined the 79th Regiment in 1857, received his captaincy ten years later, and retired from the Army in 1869, after having served for some time in India. He was a keen student in many branches of knowledge; among other things he took a deep interest in the study of languages, including French, German, Italian, Russian, and modern Greek.

GENERAL NOTES.

OUTPUT OF COAL IN GREAT BRITAIN, 1915.—The total value of the minerals raised in 1915 amounted to £170,460,949, an increase of £24,597,917, as compared with 1914. The total output of coal was 253,206,081 tons, and the value £157,830,670, showing a decrease in the output of 12,458,312 tons, and an increase in the value of £25,233,817 on the figures for 1914. The average price of coal was 12*s*. 5·60*d*. per ton in 1915, as compared with 9*s*. 11·79*d*. in 1914. The quantity of coal exported, exclusive of coke and manufactured fuel and of coal shipped for the use of steamers engaged in foreign trade,

was 43,534,560 tons. France received over 17½ million tons, Italy over 5¾ million tons, Denmark over 3 million tons, Sweden over 2½ million tons, Norway over 2½ million tons, the Netherlands over 1¾ million tons, the Argentine over 1½ million tons, Spain over 1½ million tons, and Egypt over 1¼ million tons. The total quantity exported from the country was 59,951,925 tons, as against 80,993,890 tons in 1914.

War Office Contracts.—Some remarkable figures have been published showing the enormous quantities ordered on War Office contracts from August 4th, 1914, to December 31st, 1916 (including contracts by the War Office on behalf of the Allied Governments):—

Boots	34,524,000	pairs.
Cap comforters	13,326,000	
Drawers, cotton	5,689,000	pairs.
,, woollen	20,959,000	,,
,, flannel	1,037,000	,,
,, cotton and woollen, short	1,584,000	,,
Gloves, woollen	8,382,000	,,
Socks, worsted	63,565,000	,,
Vests, woollen	9,401,000	
,, flannel	974,000	
Blankets	21,175,000	
Cloth for jackets	42,330,000	yards.
,, trousers	23,687,000	,,
,, great coats	21,558,000	,,
Barathea	2,360,000	,,
Bedford cord	2,305,000	,,
Whipcord, drab	6,064,000	,,
Flannel for shirts	105,102,000	,,
,, hospital and miscellaneous	7,244,000	,,
Duck, tent, cotton	38,060,000	,,
Drill, khaki, cotton	20,870,000	,,
,, drab, cotton	40,516,000	,,
Cotton, grey	11,041,000	,,
Jean, cotton	46,853,000	,,
Flannelette, cotton	23,344,000	,,

Calcium Cyanamide in Canada.—Calcium cyanamide is manufactured on the Canadian side of Niagara Falls by causing a current of atmospheric nitrogen to pass over powdered calcium carbide made red hot in an electric furnace. The Canadian production of calcium cyanamide is at present about 48,000,000 lb. annually, and is rapidly increasing to meet a growing demand. Nearly the whole quantity is exported. Its chief use is as a nitrogenous fertiliser, but it is also used in the production of sulphuric acid. The total value of Canadian fertilisers exported in 1915 was $2,539,789, but this included not only calcium cyanamide, but also sulphate of ammonia produced in the by-product coke ovens of the great iron and steel plants, and small quantities of other fertilisers.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

March 14.—Dr. J. Augustus Voelcker, "Fertilisers and their Supply in War Time." A. D. Hall, F.R.S., Member of the Development Commission, and late Director of the Rothamsted Experimental Station, will preside.

March 21.—G. W. Jones, "Colour Printing, and some Recent Developments." Carmichael Thomas, Chairman of the *Graphic* and *Daily Graphic*, will preside.

April 18. — Horace M. Thornton, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

April 25.—Sir Francis Fox, M.Inst.C.E., "Flour and Bread." Captain Charles Bathurst, M.P., Parliamentary Secretary, Ministry of Food, will preside.

May 2.—J. C. Shenstone, F.L.S., M.P.S., "Herb-growing in the British Empire: its Past, Present, and Future."

May 9.—Professor William Ripper, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m.:—

April 19.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

Dates to be announced later:—

D. T. Chadwick, I.C.S., "The Future of Indian Trade with Russia and France."

Surgeon-General Sir C. Pardey Lukis, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

Colonial Section.

Tuesday afternoon at 4.30 p.m.:—

May 1.—Philippe Millet, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

Sir C. Arthur Pearson, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

ALDRED LECTURES.

Monday afternoons, at 4.30 p.m. :—

LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." Three Lectures.

Syllabus.

LECTURE II.—MARCH 12.—The designing of modern monuments—Architect and sculptor—Influence of setting—Adoption of historical styles—Choice and treatment of materials—Brass, stone, marble, wood, lead—Lettering—Heraldry—Emblems and symbols—Christian feeling in memorial art—Crosses and Calvaries—The churchyard.

LECTURE III.—MARCH 19.—Equestrian figures—Group memorials—Public school, regimental and civic monuments—The War memorial—Teuton *versus* Latin spirit in design—The Christ of the Andes — Columns and arches — Buildings and bridges—Monumental art and town planning.

HOWARD LECTURES.

Monday afternoons, at 4 p.m. :—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies." Two Lectures. (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market

April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Aldred Lecture.) Mr. L. Weaver, "Memorials and Monuments." (Lecture II.)

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 6.45 p.m. Messrs. F. Gill and W. W. Cook, "The Principles involved in Computing the Depreciation of Plant."

Brewing, Institute of (London Section), at the Birkbeck Café, High Holborn, W.C., 7.30 p.m. Mr. S. K. Thorpe, "Insurances—Marine, War, and Fire—on Barley, etc."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Discussion on Mr. E. Savill's paper, "The Defence of the Realm (Acquisition of Land) Act, 1916."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. (Vernon-Harcourt Lecture.) Mr. E. Crammond, "Foreign Trade and its relation to the Investment of Capital Abroad."

TUESDAY, MARCH 13...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7 p.m. Mr. G. A. Juhlin, "Voltage Regulation of Rotary Converters."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Dr. F. W. Thomas, "The Training of the Sanskrit Poet."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. W. Gregory, "Geological War Problems." (Lecture I.)

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. J. M. Orr, "A Plea for Mural Painting."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. D. Seth-Smith, "The Photography of Wild Animals in Captivity."

Prehistoric Society of East Anglia, at the Anthropological Institute, 50, Great Russell-street, W.C., 2 p.m. 1. Presidential Address by Dr. A. E. Peake. 2. Mr. R. A. Smith, "Plateau Deposits and Implements." 3. Mr. J. R. Moir, "The Position of Prehistoric Research in England."

Anthropological Institute, 50, Great Russell-street, W.C., 5.30 p.m. 1. Address by the President, "Some Prehistoric Questions." 2. Mr. A. L. Lewis, "The Menhirs of Madagascar."

WEDNESDAY, MARCH 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. J. A. Voelcker, "Fertilisers and their Supply in War Time."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. L. Hodgson, "Air Screws."

Oriental Studies, School of, London Institution, Finsbury-circus, E.C., 5 p.m. Dr. T. W. Arnold, "The Study of Arabic."

Public Health, Royal Institute of, 37, Russell square, W.C., 4 p.m. Dr. E. L. Collis, "The Protection of the Health of Munition Workers."

THURSDAY, MARCH 15...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. C. E. Jones, "The Preparation of Plants for Exhibition." 2. Dr. R. R. Gates, "A Systematic Study of the North American Melanthaceæ from the Genetic Standpoint."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Misses C. Agutter and E. M. Smith, "Vocational Guidance in the School."

Chemical Society, Burlington House, W., 8 p.m. Lecture by Dr. H. T. Brown.

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Dendy, "Sponges: a Study in Evolutionary Biology." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. C. H. L. Emanuel, "The Light Side of Photography."

Historical Society, 22, Russell-square, W.C., 5 p.m. Rev. H. Gee, "The Derwentdale Plot (1666-1668)."

Numismatic Society, 22, Albemarle-street, W., 6 p.m.

City of London College, White-street, Moorfields, E.C., 5.30 p.m. Mr. W. E. Warner, "Refrigeration in the Fish Trade."

FRIDAY, MARCH 16...Royal Institution, Albemarle-street, W., 5.30 p.m. Sir John Stirling-Maxwell, "Scientific Forestry for the United Kingdom."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Tuscan and Umbrian Art of the Renaissance." (Lecture IX.)

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. 1. Sir W. Beardmore, "Heat Treatment of Large Forgings." 2. Mr. H. B. Ashdown, "Heat Treatment of Steel Forgings."

SATURDAY, MARCH 17...Royal Institution, Albemarle-street, W., 3 p.m. Dr. C. W. Saleeby, "Imperial Eugenics—Saving the Future." (Lecture II.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 9, 1917.

Journal of the Royal Society of Arts.

No. 3,356. VOL. LXV.

FRIDAY, MARCH 16, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

DEATH OF H.R.H. THE DUCHESS OF CONNAUGHT.

The Fellows of the Royal Society of Arts will desire to offer their respectful condolence to H.R.H. the Duke of Connaught, the President of the Society, on the occasion of the lamented death of his beloved and popular Consort.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 19th, at 4.30 p.m. (Aldred Lecture.) LAWRENCE WEAVER, F.S.A., "Memorials and Monuments." (Lecture III.)

WEDNESDAY, MARCH 21st, at 4.30 p.m. (Ordinary Meeting.) G. W. JONES, "Colour Printing, and some Recent Developments." CARMICHAEL THOMAS, Chairman of the *Graphic* and *Daily Graphic*, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1917 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 24th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

1864, Sir Rowland Hill, K.C.B., F.R.S.

1865, His Imperial Majesty, Napoleon III.

1866, Michael Faraday, D.C.L., F.R.S.

1867, Sir W. Fothergill Cooke and Sir Charles Wheatstone, F.R.S.

1868, Sir Joseph Whitworth, LL.D., F.R.S.

1869, Baron Justus von Liebig.

1870, Vicomte Ferdinand de Lesseps, Hon. G.C.S.I.

1871, Sir Henry Cole, K.C.B.

1872, Sir Henry Bessemer, F.R.S.

1873, Michel Eugène Chevreul.

1874, Sir C. W. Siemens, D.C.L., F.R.S.

1875, Michel Chevalier.

1876, Sir George B. Airy, K.C.B., F.R.S.

1877, Jean Baptiste Dumas.

1878, Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

1879, Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

1880, James Prescott Joule, LL.D., D.C.L., F.R.S.

1881, Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.

1882, Louis Pasteur.

1883, Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

1884, Captain James Buchanan Eads.

1885, Sir Henry Doulton.

1886, Samuel Cunliffe Lister (afterwards Lord Masham).

1887, HER MAJESTY QUEEN VICTORIA.

1888, Professor Hermann Louis Helmholtz.

1889, John Percy, LL.D., F.R.S.

1890, Sir William Henry Perkin, F.R.S.

1891, Sir Frederick Abel, Bt., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

1892, Thomas Alva Edison.

1893, Sir John Bennet Lawes, Bt., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

1894, Sir Joseph (afterwards Lord) Lister, F.R.S.

1895, Sir Isaac Lowthian Bell, Bt., F.R.S.

1896, Professor David Edward Hughes, F.R.S.

1897, George James Symons, F.R.S.

1898, Professor Robert Wilhelm Bunsen, M.D.

1899, Sir William Crookes, O.M., F.R.S.

1900, Henry Wilde, F.R.S.

1901, HIS MAJESTY KING EDWARD VII.

1902, Professor Alexander Graham Bell.

1903, Sir Charles Augustus Hartley, K.C.M.G.

1904, Walter Crane.

1905, Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.

1906, Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.

1907, The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.

1908, Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.

1909, Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.

1910, Madame Curie.

1911, The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.

1912, The Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.

1913, His Majesty King George V.

1914, Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.

1915, Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.

1916, Professor Elias Metchnikoff.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 14th, 1917; Edward Packard, F.C.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brunjes, Thomas Alfred, F.C.S., M.S.C.I., 94 Waller-road, New Cross, S.E. (14)

Casson, Herbert N., 4, Lincoln's Inn Fields, W.C. (2)

Gardiner, Frederick Ambrose, F.L.S., 12, The Ridgeway, Golder's Green, N.W. (4)

Hyett, John E., A.R.C.A., 4, St. Oswald's Studios, Sedlescombe-road, West Brompton, S.W. (10)

Noronha, Edward Joseph, J.P., Messrs. Noronha & Co., Hong-Kong, China.

Vickery, James Harris, LL.B., 4, Lincoln's Inn Fields, W.C. (2)

The following candidates were balloted for and duly elected Fellows of the Society:—

Bartle, George William, M.I.Mar.Eng., A.M.I. Mech.E., 27A, Mile End-road, E. (1)

Das, Manmatha Nath, B.A., A.M.I.Mech.E., 19, Waverley House, Kenton-street, Russell-square, W.C. (1)

Edwards, R. Jestyn, Brynawel, Alltwen, Pontardawe, Glamorgan.

Wolseley, Lady, Wolseley, Stafford; and Brown's Hotel, Albemarle-street, W. (1)

The paper read was—

FERTILISERS AND THEIR SUPPLY IN WAR TIME.

By John Augustus Voelcker, Hon. M.A.(Camb.), Ph.D., F.I.C.

The nation has just begun to wake up to the fact that agriculture is an essential, perhaps the most essential, industry. Hitherto it has been neglected and made to give place to almost every other interest; but now that we are going through a terrible war it is recognised, as has long been the case in Germany, that the question of the supply of food from within a country's own borders is one of vital importance.

The farmer is now called upon to produce more food, and anyone acquainted with agriculture knows that this cannot be done without the use of fertilisers of one kind or another. Where land has been so long under cultivation as is the case with the arable land in the United Kingdom, reliance can no longer be placed on the natural fertility of the soil, and for long it has been recognised that whatever benefit may accrue from crop-growing can only come from the extra crop obtained by judicious manuring.

The call for greater food production comes at a time when the farmer is, perhaps, the least prepared for it. Hampered by uncertainties as to prices, with depleted labour, shortage of machinery, and other factors into which I must not enter, he is faced with the additional difficulty which it is my province now to deal with—the shortage and high prices of all kinds of fertilisers. Nor is the trouble to be laid to the charge of the manufacturer of artificial fertilisers, for he in his turn finds himself surrounded by exceptional difficulties in the scarcity and heavy cost of transport of both raw and manufactured produce, shortage of labour, and, primarily, the fact that he is unable to obtain the supply of sulphuric acid which is so essential to him in his manufacture of superphosphate and other dissolved manures, in order to meet the farmers' requirements. These causes have all combined to raise the cost of fertilisers to figures quite unprecedented, while they have also reduced the supply to such an extent as to make them often almost unprocurable. It is a matter of common knowledge that a farmer wishing to use superphosphate for a corn or root crop may have to wait quite three months before he can expect to have it delivered to him; while the supply of other fertilisers, such as basic slag, is so limited that he may even be unable to get them at all. This, in face of this urgent call to produce more food for the maintenance of the nation at this time of crisis, invests my subject to-day with special importance.

It is not my intention to detain you with a consideration of the importance of fertilisers in our agricultural system, nor to illustrate the uses and methods of action of different fertilisers, nor, again, to draw comparisons between the use of them in this country as against others,

but I intend to go straight to the point at issue —what are the present conditions of supply, what are the needs, and how can these be best provided for?

While there are many chemical constituents which exercise an influence upon plant life and growth, those which are most directly concerned in crop-production of the farm are phosphoric acid, nitrogen, potash, and, to a lesser extent, organic matter or humus, and lime. So far as the manufacture of artificial fertilisers goes, this is, for all practical purposes, concerned with the supply of phosphoric acid, nitrogen, and potash; and with these I shall mainly occupy myself, and deal with them in order.

The most common of all fertilisers is, of course, farmyard manure, comprising in itself the foregoing three constituents as well as organic matter and other bodies. The supply of it is, however, a regularly decreasing one, and the great rise in the price of feeding-stuffs experienced since the war began has made it increasingly expensive to produce. As a consequence, dependence will more and more have to be placed on artificial fertilisers. Some of these, as, *e.g.*, superphosphate, aim at providing one constituent only, phosphoric acid, in one form or another; so with nitrate of soda and sulphate of ammonia, which provide nitrogen; whereas others aim at combining both these ingredients and occasionally potash as well. While it is not possible to divide them strictly into classes, we may yet well consider them from the point of view of what they mainly supply.

A.—PHOSPHORIC ACID.

To take, first, fertilisers that mainly supply phosphoric acid. We have under this head superphosphate, basic slag, and ground phosphates, as calling at the present time for most attention. In fact, one might say that for all practical purposes the present-day question of the supply of phosphatic fertilisers resolves itself into that of providing superphosphate and basic slag. True it is that there are other materials, such as bones in their different forms, guanos, such as Peruvian and meat and fish guanos, which may help towards meeting the phosphatic supply, and there is also the great group of "compound manures," which are all more or less phosphatic in composition, but bones and guanos are restricted in their supply and use, and "compound manures" may be regarded as "variants" of the more widely used superphosphate, of which, indeed, they are often largely composed.

Superphosphate.

Superphosphate may indeed be taken, under existing circumstances, as the type of dissolved phosphatic manures, just as basic slag may be regarded as that of the raw or undissolved. It is long since Liebig first showed the great advantage of treating bones with sulphuric acid, thus rendering the phosphate of lime soluble and enabling it to act more quickly upon the crop; while Lawes, following up the discovery and applying it to ground mineral phosphates, laid the foundation of the great "superphosphate" industry which has flourished to this day. The attempt has often been made to utilise raw phosphatic materials by grinding them finely and spreading them on the land, but until the advent of basic slag this has never met with any marked success, and it has been found much the more profitable way to convert the phosphate into superphosphate. The advantage of this is well seen in growing a turnip crop, the application of the readily soluble and quickly-acting phosphate enabling the young plant to push on in its early stages and thus escape the ravages of the "turnip-fly."

I have spoken of "compound manures" as being practically "variants" of superphosphate with the addition of other materials of a nitrogenous and occasionally potassic nature as well, and, as I do not intend to refer to these again, I may dismiss them by saying that their main purpose is to save the farmer trouble. I will not deny that in many cases they are carefully and intelligently compounded, and sometimes with due regard to the crop for which, and the soil on which, they are to be used. But I cannot pretend that I place, as a rule, much store upon the fact that this manure is called "wheat manure," the other "barley manure" or "oat manure," and that others are described as "turnip manure," "mangold manure," and so forth. In reviewing circulars in which these manures are set out with their respective analyses, I am often at a loss to know wherein the differences between them really lie, and I should not be disposed to share the anxiety of the farmer who found that by some mistake he had applied "oat manure" to his barley crop instead of "barley manure," or had put "mangold manure" on his swedes! In Germany—where, by the way, fertilisers are used to a very much greater extent than in our own country—the farmer has assimilated very much better the teaching of agricultural science as emanating from his provincial experimental station ("Versuchsstation"), and he orders manures to supply so many pounds of phos-

phoric acid, nitrogen, etc., according to the requirements of his crop, and not merely so many tons of this or that "special manure."

Dissolved bones may well be classed with superphosphate, as may also the large class of manures known as "bone manures," these consisting generally of bones more or less dissolved, with admixture of ordinary mineral superphosphate.

The raw phosphatic materials, whether they be phosphatic rock or bones, are ground and then treated with sulphuric acid, the supply of the latter being thus all-important. Of phosphatic rock the principal sources at present are those from Northern Africa, and comprise Gafsa, Constantine, Algerian and Tunisian phosphates, Egyptian phosphate, together with some Curaçao and Ocean Island rock phosphate. The difficulties of obtaining freight militate, of course, greatly against the obtaining of large stocks of these; but, so far as I have been able to ascertain, there would seem to be sufficient raw material in stock to work up into superphosphate if the acid for so doing were available. The larger fertiliser factories make their own acid, though many of them in normal times purchase acid as well. The smaller factories distributed over the country purchase their acid. At the larger works not merely "chamber acid" of about 66 per cent. strength, such as is used for ordinary superphosphate making, is produced, but a stronger acid, of about 80 per cent. strength, is obtained from the Glover towers, and there is plant also for preparing a pure and concentrated (95 per cent.) acid, freed from arsenic, and such as is suitable for the manufacture of high explosives.

Since the commencement of the war, as is well known, all these sulphuric acid-producing works have been put under Government control, and set to produce acid as hard as ever they can. So urgent indeed has been the call for the supply of sulphuric acid for munition purposes that these works have been continuously working at full pressure, and in many cases considerable extension of plant has had to be provided, and special installation of plant for concentrating and purifying the acid. With this, in face of the country's needs, no one can complain, and it was clearly the right thing to do. But the effect upon agriculture has been serious, and has resulted practically in a "superphosphate starvation." It is reckoned that quite 50 per cent. of the acid which normally would be available for the manufacture of artificial fertilisers has been withdrawn from its general use. As a consequence, it has been impossible to work up the stocks of raw phosphatic material, and the farmer has had either to do without superphosphate, or to take his chance of when it may be delivered to him. Farmers, it must be said, are not given, as a rule, to order their fertilisers long before they require them for use, and they do not care to have them long stored at their farms; so that it is not usual, except with large farmers and the more enlightened ones, to make their contracts long beforehand. The result of this is seen now, for it may be taken that any farmer ordering superphosphate to-day would have to wait quite three months before it could be delivered to him. The factories are still going on making superphosphate as they have opportunity and acid to spare, but in many cases what superphosphate is made goes largely to form the base of the "compound manures," which offer a considerably wider margin of profit to the manufacturer than does the sale of superphosphate itself. In this connection, it is said that some of the smaller works throughout the country possess an advantage, in that they only make a weak acid which is not worth transporting, and so they are allowed to continue using it for fertiliser manufacture.

Simultaneously with this "holding up" of the acid supply comes the call to the farmer to produce more food crops, to grow more corn, to plough up grass land and put it in wheat or oats or potatoes. And now he is practically deprived of the main source which is to help him to achieve the object. The time of winter sowing of wheat has gone by, an unusually hard and prolonged winter has left the land frost-bound, and will necessarily greatly delay the period of spring-corn sowing. It is under such circumstances that the farmer will more than ever need the quickly-acting fertiliser recognised to be so necessary for his spring corn-crops, as well as for his root-crops. To ask him, then, to produce more corn, and without giving him the necessary superphosphate, etc., is, leaving aside the other difficulties that he has to contend with, like asking him to "make bricks without straw."

I shall probably be asked what remedy I have to suggest for this state of things, whether I can recommend any substitute that has been proposed for superphosphate or have any other to put forward. I cannot say that there is any adequate substitute, nor that I see any prospect of a better state of things so long as we have one Department of Government working, not along with, but sometimes directly contrary to the interests of another. I cannot but acknow-

ledge, as must every true Britisher, the paramount call for more munitions and for more men, and that it must be the first concern to "win the war." Agricultural requirements must necessarily come secondary to the provision of munitions and men, and yet one cannot but feel that there ought to be a better interworking among Government Departments, for while the War Department is taking men away from the land, and the farmer cannot get his fertilisers, it is hopeless to expect him to produce more food for the nation's supply. One would think that it would be possible, while maintaining the output of munitions at the necessary rate, to spare enough sulphuric acid for the regular manufacture of fertilisers, though the supply of these may have to be limited. So far as the farmer is concerned, it is not a matter of price, it is the sheer inability to provide him with what he requires. Nor can the blame be put upon the manufacturer, for there is no reason to think that he is profiting by the larger outturn of acid, but that he would prefer, if he could, to meet the agriculturists' requirements. This is especially felt in places where manure factories have been established in country districts by the farmers and are largely maintained for their benefit. I am glad to learn within the last few days that arrangements are now in contemplation by which not only it may be possible to set free a larger supply of sulphuric acid for fertiliser manufacture, but also to provide for the shipment of more raw phosphatic material, the stocks of which, though not actually run out, are considerably depleted, and will need replenishing in view of the requirements of another season. This is, clearly, what should be done.

Substitutes for Superphosphate.

As a substitute for superphosphate there has been put forward what is known as "war-time superphosphate." Under this name is sometimes sold a mixture of superphosphate and ground mineral phosphate, half and half, with rather less than half the amount of "soluble phosphate" that superphosphate has. As a way of eking out the limited supply of superphosphate this is quite a good "makeshift," though it may be expected to "go back," on keeping, to the extent of, say, 3 to 4 per cent. in "soluble phosphate."

Another plan of making "war-time superphosphate" has been strongly urged by the Board of Agriculture upon makers of artificial manures, and that is to utilise, for dissolving purposes, the free sulphuric acid present in "nitre-cake"—a material produced in the manufacture of sulphuric acid, it being the residue left after treatment of nitrate of soda with sulphuric acid, thereby giving nitric acid for the evolution of the nitrous gases which pass into the chambers. This residue is essentially a sulphate of soda which contains something like 30 per cent. of free sulphuric acid, together with variable quantities of nitric acid compounds. The free acid, it has been suggested, might be utilised to replace or at least to supplement the acid available for dissolving use.

In some cases manufacturers have simply ground up the nitre-cake and have mixed with it ground mineral phosphate, and called this "war-time superphosphate." This, to my mind, is a wrong statement, and the material should not be called "superphosphate." The acid sulphate of soda will not decompose the phosphate rock by merely mixing the two materials together, and it is only when water or acid is added that there is any real reaction.

But where sulphuric acid has been used along with the nitre-cake the case is different, and here a considerable proportion of the phosphate may be rendered soluble. There are, however, great difficulties experienced in dealing with these materials, and it is hard to obtain a product in good condition and free from pastiness. The matter is very rightly engaging attention, and, though some manufacturers have said they cannot "work" it, others have met with some share of success. Could a waste product like nitre-cake be utilised in this way it would undoubtedly, when acid is scarce, be a great boon and supplement the supply of acid. Unfortunately, however, all such attempts require extra labour, and, possibly, additional plant, and this at a time when the manufacturer can least afford either.

I shall revert to this question of the utilisation of nitre-cake when dealing with sulphate of ammonia manufacture.

Ground Phosphates and Basic Slag.

Though these represent two quite different classes of phosphatic materials, it will be convenient to group them together, for, in the assessing of their value on the land, come in two considerations which have not until recent years entered. These are (*a*) fineness of grinding, (*b*) solubility in citric acid solution.

It has been mentioned that treatment of phosphate rock with sulphuric acid was found to render the phosphates far more available, and

though attempts were made in the early days by Aitken and others to utilise ground mineral phosphates as direct applications to the land, these never obtained much success. It is probable, however, that the fineness of grinding now reached in the case of basic slag was not then attainable, for experiments have more recently been put forward in which it is maintained that some class of mineral phosphates, if ground as finely as basic slag generally is, will answer just as well. However this may be, it remains the case that phosphates are but little used without treatment, but that basic slag is. It behoves us, therefore, to examine more in detail the claims put forward in regard to basic slag. This, as is well known, is the slag produced in the Thomas-Gilchrist process of dephosphorising iron, a process particularly adapted to ores containing phosphorus, the removal of which is necessary in order to make a good steel. The Bessemer converter is lined with magnesian lime, and in the process of conversion a slag forms, which is run off, and in this the phosphorus is found, occurring, some say, as a tetra-basic phosphate of lime, others as a silico-phosphate of lime. For a considerable number of years this slag accumulated in great heaps at the works, for, though tried on the land, it never seemed to do any good. It was then that the plan of grinding it very finely was tried, and the results, at least on grass land, were of a most striking nature. From that time on, the accumulated heaps of basic slag were worked and ground down for agricultural use, and it is only right to say that hardly any discovery within the last thirty years in the practical line has proved so useful agriculturally as has that of the utilisation of basic slag. It was in Germany, however, that it received its special impetus, alike by the business energy of its promoters and the advocacy of the well-known agricultural chemist Wagner. Indeed, this advocacy is responsible for some claims of doubtful value put forward for basic slag. The first idea was to "push" it as against the universally-employed superphosphate, and to aid in this there was utilised the discovery made by Wagner that basic slag, if treated in certain proportion with citric acid of certain strength and for a particular time, allowed a large part of its phosphoric acid to pass into solution. This was called "citric soluble" phosphate, and the name has, mainly through the "pushing tactics" of the promoters, now practically become universal and recognised alike by the trade and by legislation. Further than this, the "solubility" in the particular solution recommended by Wagner and under the particular conditions which he set out, has come to be the test for what is called the "available" phosphoric acid in basic slag, no other phosphate than this being recognised as possessing any appreciable manurial value.

I have myself always been opposed to this view, and to the practice it has given rise to. The most that I could see my way to was to admit that, on general grounds, one might say that the phosphate which was soluble in a weak organic acid might be expected to be more readily available for plant use than that not so dissolved. But to allow this as a quantitative measure of value I could never consent. Nor, seeing that citric acid does not exist in the soil, and that roots do not obtain their food from the soil by means of it, and that the soil is not in contact with the basic slag for half an hour only but for many half hours, do I see the wisdom of tying oneself down to a purely arbitrary and conventional method of procedure. It is well known that a different strength of citric acid employed, and different conditions used, would give totally different results, and, more recently, it has been shown that successive treatments of ground phosphate rock with citric acid will remove practically the whole of the phosphate. Why then a particular organic acid of a particular strength, and employed for a particular period, should become the test of value of basic slag I do not see. It would be much more reasonable to take carbonic acid as the solvent, inasmuch as this does occur in the soil, and exercises a great influence in rendering the constituents of the soil available. Still less do I see why other basic slags, which do not conform so readily to this test, should be rejected as worthless or nearly so, and without a practical trial of them.

So hard, however, has the "citric-soluble" doctrine been "run," and primarily from purely commercial and interested motives, that it has become an "article of faith." The practical outcome of this is that though large quantities of slag are produced in this country by the "open-hearth" process, and though these contain quite considerable amounts of phosphoric acid, they are not utilised, simply because they are less soluble in a 2 per cent. citric acid solution than those coming from the Bessemer process. Not only this, but so strongly were the "citric-soluble" views insisted upon, that, previous to the war,

it was the custom to import basic slag from the Continent for use here; and now that this import is stopped we have a great shortage in our basic slag supply, for, though not absolutely unprocurable, it only comes forward in limited amounts and at uncertain intervals. This, to my mind, when basic slag is so much required for pastures and production of meat, is very regrettable, especially in view of the fact that tons and tons of basic slag are lying about unutilised, and mainly because they do not conform to the "citric-soluble" test. I certainly feel strongly that these lower-quality slags ought to have a more thorough trial given to them, and not be dismissed as useless.

The fact is that there is something very peculiar about the action of basic slag, and this no chemist has yet been able fully to explain. The benefits have been variously attributed to the fineness of grinding, to the presence of lime, to the "citric-soluble" phosphate, etc.; but none of these is in itself sufficient to explain its value. Judging bone dust or precipitated phosphate by these standards, they should prove as efficacious, and yet everyone knows that this is not so. Again, no adequate explanation is forthcoming of the recognised fact that it is on grass land, essentially, that basic slag works often such wonders, and more especially on cold heavy soil, whereas on light soil it frequently is entirely without benefit if used by itself. Why should these undisputed results follow its employment on grass land and not be equally apparent on arable crops? I frankly confess I have never yet been able to say on what land basic slag is likely to answer; the only advice I can give is to "try it," and, if it answers, use it freely. But, though many experiments have been tried with it in comparison with other fertilisers, I am not satisfied that any of these have yet pointed to the real cause of success; for all I know, it may yet be found in some or other of the more or less neglected constituents of basic slag. Equally unsatisfactory, to my mind, are the experiments—especially those of Wagner himself—which have sought to establish the value of basic slag as resting in the "citric-soluble" phosphate. There is, then, something very peculiar about basic slag which makes experimenting with it a very difficult matter, and in my own experiments, alike on high-grade and on low-grade slags, and on high citric-solubility and low, I have not as yet succeeded in getting results that convince me. In face of this and the national needs, I repeat, therefore, that the accumulated stocks of lower-grade and lower-solubility basic slag should be worked up and made available for the farmers' use. In a recent paper Professors Gilchrist and Louis, of Newcastle-on-Tyne, estimate that in this country there are 740,000 tons of "open-hearth" slag as against 120,000 tons of Bessemer slag. In Germany, on the other hand, previous to the war, the Bessemer slag produced considerably exceeded the "open-hearth" slag, and so it was to trade interests to push the "citric-soluble" system of valuation.

If my remarks as to citric solubility tell against basic slag, how much more should they against a material which, though sold under the name "basic phosphate," and stated to contain "soluble phosphates," and to be a "substitute for superphosphate," is nothing more than ground mineral phosphate, advantage being taken of the fact that, by using a very little of it with a very large volume of very dilute citric acid solution, the greater part of the phosphates will be rendered soluble. This is to bring the whole test, and any merit that may be attached to it, into disrepute; and it shows, further, the evil of extending the term "soluble phosphate" to other than what is soluble in water, as in the case of superphosphate.

Bones and other Phosphatic Materials.

In superphosphate and basic slag I have dealt with the principal phosphatic manures that the farmer requires—the former for his arable crops, the latter for his pasture. To a far lesser extent come in bones in their different forms—fish and meat guanos, and Peruvian guano. Then there is the whole class of "compound manures," which, though not purely phosphatic, are so in their basis, and may be considered with superphosphate. Bones have of late been coming somewhat freely from the camps in France and elsewhere, and may be obtained either ground into bone-meal, steamed to remove the gelatin and sold as "steamed bone flour," or, again, treated with sulphuric acid to form "dissolved bones" or the different varieties of "bone manure." As with all other fertilising materials, the price of bones has gone up tremendously, and what before the war cost £6 or £6 10*s*. per ton, cannot be had now for less than £9 or £9 10*s*. per ton. Bones, moreover, are valuable, in no small measure, because of their more "lasting" effect; but this, at a time when the country requires the rapid production of food crops, is not of so

much consequence, and the farmer naturally turns to the cheaper and quickly-acting superphosphate. For the same reason basic slag is not so likely to be used for arable crops if other supplies are available, and in any case it is known that it must be applied early. The severe and prolonged winter will make the preparation of the land for spring-sown crops both difficult and late, and so the need of a quickly-acting fertiliser like superphosphate will be all the more felt.

Fish guano and meat guano are used mainly for special crops like fruit, hops, etc., and do not affect the general agricultural supply largely. Fish manure may still, I hear, arrive from local sources, but the import of meat guano (from the River Plate) is practically closed for the present. Of Peruvian guano there are still some stocks left, and this fertiliser can be purchased either as "raw," "equalised," or "dissolved" Peruvian guano. Its price has hardly risen proportionately to that of other fertilisers, and the fact that it combines at once phosphates, ammonia, and potash in active forms makes it still a favourite with many, and now, when potash salts are not generally available, the presence of potash in this natural fertiliser is not to be ignored.

It will be seen from this summary of the position, that superphosphate and basic slag are the two phosphatic fertilisers that the farmer is in need of, and with which he must be supplied if he is to contribute materially to an increased yield of corn and meat.

B.—NITROGEN.

To one who, like myself, has been "brought up" on the "Nitrogen question," and has carried out many inquiries on, and entered into many discussions about, the relative forms of nitrogen in fertilisers and their respective values, it is somewhat amusing to find how the question has, under the stress of the war, resolved itself as a practical measure into the supply of one material only, viz., sulphate of ammonia. And this because sulphate of ammonia is the one home product. For phosphates, the limited stores of coprolites found in this country have long had to give place to richer materials from abroad which allow of more ready and economical manufacture. Sulphate of ammonia, though a home product, has been, I will not say neglected, but only thought of on the basis of how it stood in comparison with nitrate of soda or other nitrogenous sources, and without any regard to whether we might not some day have to depend on our own products. Farmers are no different from other folk in this respect. The matter of cost, and not the Imperial outlook, has been the guiding feature in all our transactions. Now, however, that we are reduced to it, we ought to be thankful that there is such a supply available and in such profusion, but equally so it behoves our Board of Agriculture and the Government generally to see that the supplies we require are kept for the country's use.

Nitrogen, it has been recognised since the days of the noted controversy of Lawes and Gilbert with Liebig—the advocate of the "mineral theory"—is the constituent upon which our corn crops particularly depend for their rapid growth when the advent of summer sets them "going," and nothing has been found so effectual for their rapid "pushing on" at this stage as have nitrate of soda and sulphate of ammonia. Fierce often has been the struggle between these for recognition, advocates of the merits of one against the other have been legion, volumes have been written about them, experiments galore, till we have finally settled down to regard it as—in most cases—more a matter of the price at which we could purchase the unit of nitrogen in each than of anything else. Now, however, has come in the war to settle, for the time at least, the question between the rivals—for nitrate of soda is to all intents no longer available for agricultural purposes. Added to the difficulties of shipment—it all coming from the west coast of South America—is the fact that it is all required in connection with the manufacture of explosives, either directly or for making the all-essential nitric acid. When procurable at all, its price is £21 to £22 per ton, which, compared with sulphate of ammonia, now at £16 per ton, and containing one-third more nitrogen per ton, puts it "out of court."

As between the two sources of nitrogen, it may be said generally that, though nitrate of soda was perhaps the favourite one with farmers, they will suffer little or nothing by the enforced change. The superiority of one or the other is mainly a matter of season and of price, and, to some lesser degree, of the land and the crop. Sulphate of ammonia is a few days slower in its action, but is preferable on clay lands, just as nitrate of soda is to be chosen for chalk soils. Sulphate of ammonia is less readily washed out and so does better in a wet season, and nitrate of soda in a dry. For certain crops, *e.g.*, potatoes and sugar-cane, sulphate of ammonia

is to be preferred; for a hay crop, nitrate of soda. But, as stated, the differences between their action are not such as to interpose any real difficulty now that only sulphate of ammonia is available.

Other nitrogenous supplies will be briefly noted later, but do not exercise any real influence on the question of the moment, which, as regards nitrogen, centres upon sulphate of ammonia just as the phosphatic supply was found to hinge upon superphosphate and basic slag.

Sulphate of Ammonia.

Sulphate of ammonia, as is well known, is prepared from the ammoniacal liquors produced in the distillation of coal in gasworks and coke ovens, and from shale and ironworks, etc. A few only, and these the larger gasworks, make their own sulphuric acid from the spent oxide used in the removal of sulphur in gas purification; but the majority, and practically all the country works, purchase their acid. The smallest works of all, indeed, do not work up their liquor, but send it elsewhere.

In face of the facts recorded it is evident that it becomes a question of the highest moment that the sulphate of ammonia produced in this country should be retained, so far as our requirements go, strictly for use here. Some considerable amount is used for munitions, but what remains after this paramount need is supplied should be reserved for agricultural use. Until recently, when, on January 19th, the export of sulphate of ammonia was prohibited altogether, the question of export has been a "burning" one between manufacturers (with traders) and agriculturists.

The removal of competition in prices with nitrate of soda and the shortened supplies no doubt offered favourable inducements to export, and to this were added the advantages that the stock could be at once disposed of, the money obtained and so kept in busy circulation. On the other hand, the agriculturists and the manure manufacturers urgently required it, and, ultimately, in August 1916 the Board of Agriculture arranged with the Sulphate of Ammonia Association that farmers could obtain sulphate of ammonia until the end of September at the price of £15 per ton for immediate removal, the price for the 1916–17 season being £15 10*s*. per ton. It would appear that, previous to this, farmers had not sufficiently availed themselves of the opportunities of laying in their needed supplies. For this there were several reasons: for instance, a farmer seldom has the facilities for storing any considerable quantity of manure on his farm, and he does not care to order it long before he knows exactly what his requirements will be, while, added to this, is the expectation that prices may be more favourable. These two sets of conditions, as affecting the traders on the one hand and the farmers on the other, acted favourably to the desire for export; and it is to be noted that the total exports in July-December 1916 were only 2,900 tons less than in the corresponding period of 1915. Along with this is the significant fact that, while the exports to Spain, Holland, Java, West Indies, Japan, and the U.S.A. were less in 1916 than in 1915, and naturally more to France, there was an increased export in 1916 of 12,500 tons to "other countries" (this meaning Scandinavia and mainly Norway) over that of either 1915 or 1914. One can scarcely resist drawing the conclusions that a not inconsiderable amount of sulphate of ammonia produced in this country found its way during 1916 to countries where it should not have gone, and, further, that in the production of this a not inconsiderable amount of sulphuric acid was being used at a time when the manure manufacturers were not able to retain enough of it to make superphosphate for the farmers' needs. One may have a certain sympathy with the maker of sulphate of ammonia in that by export he turns his money over and has not to store his goods, whereas if he sells to the farmer the latter will want him to keep it for him until he is ready to use it; but in these days one ought to be patriotic, and it is not right that the only available nitrogenous manure should be sent out of the country, more especially if it has been made by using the acid of which the manure manufacturer is deprived.

Now, however, by the order of January 19th, 1917, this has been put right, the export of sulphate of ammonia being altogether prohibited, and a price of £16 per ton (£15 10*s*. per ton at the works) being fixed. While, however, expressing satisfaction at this, I must say that I do not think it would have been unreasonable to call upon the farmer to state by a certain date what his probable requirements would be, and to ensure that sufficient stock be kept over to meet these. A further matter that has been pointed out to me is that the concession to the manure manufacturer to buy sulphate of ammonia at 10*s*. a ton less is hardly sufficiently liberal to recoup him for the extra cost of handling, storing, etc.

When dealing with substitutes for super-

phosphate I mentioned that the use of nitre-cake had been urged by the Board of Agriculture on superphosphate makers. I would now ask why it should not have been equally urged upon makers of sulphate of ammonia where the product is to be used as a fertiliser? One can understand why it should not be employed when munitions are concerned, but there is no absolute need for a farmer to have a 24 per cent. or 25 per cent. ammonia "sulphate." A much lower quality would do quite well, and the presence of the sulphate of soda would not constitute a bar. I am aware, of course, that there would be difficulties with this, but probably not greater ones than exist in making superphosphate with nitre-cake, and, if necessary, the salt could be purified by recrystallisation. I have examined samples of sulphate of ammonia thus made and containing over 24 per cent. of ammonia.

Other Nitrogenous Supplies.

Of late years other forms of nitrogenous fertilisers, produced directly from the nitrogen of the atmosphere, have come into competition with sulphate of ammonia and nitrate of soda. These are "nitrolim" (calcium cyanamide) and nitrate of lime, with, possibly, nitrate of ammonia. Since the outbreak of war these, however, have not been available for fertiliser use, and so need not be considered here, though it is believed that the two former are to a certain extent being used for munition purposes.

Other nitrogenous supplies, though all limited in use and hardly entering into the present consideration, are hoofs and horns, shoddy and wool waste, castor meal, rape dust, dried blood, soot, etc., while some of the materials already named, such as bones, fish meal and Peruvian guanos, would have to be taken in respect of their phosphatic contents also. Farmyard manure, again, is the most general one, but it is hardly a saleable article, and the supply of it is, with the increase of motor traffic, a diminishing one, and now, especially with the great rise of price in feeding-stuffs, it is increasingly expensive to produce.

C.—POTASH.

Lastly comes the consideration of potash-supplying materials, and this need not detain us long, for it is well known that since the products of the Stassfurt mines ceased to come here, agriculturists have practically had to do without potash. Much has been said and written about the providing of a substitute for these salts; but, though seaweed, the ashes of hedge-clippings, bracken and other materials have been named, none of them have, except under quite local conditions, taken actual shape. Still, from time to time, materials are brought forward that supply potash, though, so far, none of them exist in any great quantity. The refuse from beet-sugar purification, the "argol" (tartrate of potash) obtained in the fermentation of wine and the sweepings of flues in works where iron and manganese ores have been smelted, are all utilised so far as they go. The last-named material has about the same amount of potash that kainit contains (10 to 15 per cent.), the potash being present partly as sulphate and partly as carbonate. It would not appear, however, that the quantity of this available exceeds 3,000 tons annually. The present price is £7 to £9 per ton, or 7*s.* 6*d.* per unit per ton of sulphate of potash. For some time there has been talk of extensive deposits of potash salts in Catalonia (north of Spain), but nothing has so far been done to develop these. Indeed, I have heard it hinted that, previous to the war, the Stassfurt people were interesting themselves in the development of this source.

Yet another supply has been heard of in potash salts of high quality, obtained by somewhat difficult refining, from districts bordering the Red Sea. These are sold on a basis of 80 per cent. sulphate of potash, and of them about 6,000 tons annually are said to be available. Peruvian guano, as already observed, contains some amount of potash, and so may acquire a special value at this time. The review of these supplies, and the fact that we are at the present time going on with our agriculture without renewing the potash supply, naturally raises the doubt as to whether the oft-preached doctrine of potash for crops has not been "overdone." Certain it is that the land is not yet suffering a potash starvation, and when I look at the Rothamsted records in the case of heavy land, and my own on light land (though carried out for a much briefer period), I confess that I fail to see the clear evidence of potash being as urgently required as has been put forward. No doubt there are certain crops such as potatoes, mangels, clover, fruit, hops, etc., which benefit largely from the application of potash, but if farmyard manure can be supplied in sufficiency it will probably give all the potash that is wanted, while for ordinary corn crops, such as wheat, barley and oats, it is very questionable if potash is required under ordinary circumstances and

in rotation-cropping. Indeed, I confess that I am beginning to wonder whether, just as with basic slag and the "citrate solubility," the need of potash for crop-growing has not, to a great extent, been the outcome of an enterprising "trade policy" rather than a truth founded on actual facts of science and practice.

However that be, I must say that I regard far less seriously than I did at first the shortage of potash salts so far as agriculture is concerned.

D.—ORGANIC MANURES.

Little need be said as to this class, the prominent members of which have already been mentioned, such as farmyard manure, castor, rape and other meals or cake residues, together with shoddy, dried blood, hoofs and horns, etc. In such times as the present, use ought to be made of all bulky organic materials which may take the place of farmyard manure, and be useful on heavy land for opening it up, and on light land for supplying "substance" and the often deficient "humus." There is, indeed, the fear that, with the confinement of manuring to superphosphate and sulphate of ammonia, the land may be found to suffer from poverty in organic matter. Sewage waste and similar refuse substances should be used wherever possible; but, of course, such materials can only be employed when near at hand, and few of them will bear carriage by rail nowadays.

E.—LIME.

I take this lastly because experiment and experience have alike told that its use is in many cases the base of rational manuring. Without sufficient lime in the land artificial fertilisers will not effect their full benefit; superphosphate used on soils deficient in lime will produce an acid condition and give rise to "finger and toe" in turnips; sulphate of ammonia used year after year on similar land will bring about, as shown in the Woburn experiments, an acid state of the soil and in process of time absolute sterility, the remedy for which is the application of lime. At the same time I may be allowed to dissent from views expressed in a recent leaflet issued by the Board of Agriculture, in which the use of lime by itself was recommended in the event of fertilisers like superphosphate and basic slag not being procurable. Lime, useful as it is, is not to be regarded as a manure, nor as taking the place of any fertiliser. It is a material for ameliorating the condition of land, and for setting free for action various fertilising constituents in the soil or applied to it; it may also be desirable, when sulphate of ammonia is freely applied, that lime be present in the soil also; but the contingency of a soil proving sterile in the course of a few years is very remote. The trouble with lime is its bulkiness, and that it is not readily procurable everywhere, while the labour of handling, carting, etc., is likely to be much felt at this time. Still, where lime is needed, it would be a most foolish policy to dispense with it.

CONCLUSION.

I have endeavoured in the foregoing to sum up the general agricultural requirements of the present time in regard to fertilisers as consisting in the supply of superphosphate and basic slag as phosphatic manures, and of sulphate of ammonia as the nitrogenous one. The others may be left to look after themselves, but the supply of these three is all essential, and if our farmers are to meet successfully the demands now made on them, it is all important that they should be put in the way of obtaining an adequate and ready supply of these. Further, now that the prices for the crops of the next few years have been fixed ahead, it is necessary that the prices of these fertilisers should not be allowed to go above a figure at which they can be remuneratively used. This the Government has, on the advice of the Board of Agriculture, wisely decided in the case of the most expensive of all, sulphate of ammonia, and it is hoped that, if found necessary, the Board will similarly intervene in the case of the other fertilisers.

DISCUSSION.

THE CHAIRMAN (Mr. Edward Packard, F.C.S.), in opening the discussion, said that with regard to the possibility of obtaining phosphates in sufficient quantities at the present time he would remind those present that in 1914 this country imported 562,242 tons of phosphate rock of different kinds; in 1915, 374,600 tons; and in 1916 only 333,371 tons —a little more than half of what was imported in 1914. In 1915 the Munitions Department of the Government requisitioned all the sulphuric acid in the country to assist in the production of munitions, and fertiliser works gave up very nearly 50 per cent. of their total amount for national use. Naturally that affected the farmers and affected the production of food in this country. Since the food question had become acute the Munitions Department had said that they would liberate some portion of the acid so that superphosphate could be produced to a larger extent. All those connected with agriculture would be

very glad of that concession, although it came late and imposed a serious difficulty upon manufacturers. Owing to the great difficulties with regard to shipping, some parts of the country had been left absolutely bare of phosphate, while other parts had been able to secure large quantities of it—more perhaps than they needed for their immediate use. The problem at the present moment was how to transfer phosphate from places where it was abundant to those where it did not exist; even coasting vessels were now difficult to obtain for that purpose, and railways had largely to be relied upon. For instance, during the last two months phosphate had been sent by rail from the west of England to the extreme east, that being the only means of obtaining a supply in the eastern counties; that involved a serious cost and took up railway waggons at a time when they were needed very urgently for other purposes. The growing of wheat in this country might be as important next year as it was in the present year—in fact, it might require to be carried out on a much larger scale, and if that were so much larger quantities of fertilisers would be required in the autumn. He did not think farmers quite realised the advantages of applying phosphatic fertilisers to wheat in the autumn, but their application then was of great benefit to the crop. In 1868, 3,937,000 acres of wheat were grown in this country, but in 1907 that had decreased to 1,665,000 acres, the large quantity grown in the former year showing what might be done now. Wheat was certainly the most useful food that could be grown, if only a sufficient acreage could be covered. But how was the increased quantity of fertilisers necessary for a greater growth of wheat to be obtained? He saw great difficulties ahead, and he doubted very much whether the importation of phosphate rock during the present year would in any way approach the importation even of last year. If the war continued—as it probably would—for some considerable time yet, it was very important in the national interests that ships should be provided to bring phosphates to this country, in order that more food might be produced. He thought the remarkable effect of basic slag upon grass land was due to the free lime which it contained, which had an especially good effect on an acid soil. On the other hand, on an alkaline soil nitrate of soda had but little effect, but sulphate of ammonia had a very good effect—an alkaline soil responded to an acid manure.

Mr. J. W. Hughes thought it would be very interesting to know how our enemies were supplied with manures. There used to be phosphates found in Germany, but he thought those had all been exhausted now. There was no doubt about the fact that German chemists were making nitrogen from the atmosphere, but were we taking any steps in that direction? He was afraid not. He hoped the time was coming when more attention would be paid to the utilising of all the refuse on farms; and we also wanted a higher system of cultivation.

Dr. Bernard Dyer said that with regard to basic slag it was quite true that the Bessemer slag, which was better known in this country than the open-hearth slag, had a marvellous effect upon grass land that did not seem to be possessed by other forms of insoluble phosphates. He did not think that effect was due, as the Chairman had stated, to the lime it contained; he thought chemists were beginning to realise that there was not the large quantity of free lime in basic slag that it was formerly supposed to possess. It was combined lime, not free lime; and effects were produced by the use of basic slag that were not produced by dressing with finely ground lime. Another point which differentiated basic slag from other forms of insoluble phosphates was the extreme readiness with which it dissolved in dilute citric-acid solution. It did not seem altogether unreasonable—in the lack of more accurate knowledge—that there was some kind of connection between those two points. The question of whether the "citric solubility" test was really the result of agricultural experiments was raised in an acute form in Germany some years ago, and as a result, at a meeting of the directors of all the agricultural experiment stations in Germany, the whole matter was remitted to each and all of the stations for re-investigation. He understood that after an investigation lasting over a few years the German agricultural chemists had come to the decision that there was no reason to depart from the citric-acid solubility test which had been maintained since the days of Wagner. He agreed with the author that sulphate of ammonia might be made from nitre-cake, and that a lower quality of sulphate of ammonia, containing a larger percentage of soda, might quite well be used by farmers. It was well known that soda had a considerable fertilising effect, and there was good reason to believe that some of the excellent effects produced by nitrate of soda on some soils were due not merely to the nitrogen but to the action of the soda portion of the fertiliser in helping to liberate potash. He believed that even nitre-cake would be very useful on some soils as an indirect means of helping to obtain potash. He agreed with the author that the value of potash had been over-estimated, as he knew of land which had received no potash dressing for twenty years, or farmyard manure or potash-containing manure of any kind, which had yet grown splendid crops of some kinds of vegetables, provided that it was supplied with nitrogen and phosphates. As regards potatoes, the non-application of a hundredweight of sulphate of potash had made in twenty consecutive years an average difference of one or two tons of potatoes an acre. Potash salts were useful in the case of

potatoes, and when they could not be obtained farmyard manure should be used, and withheld from such things as turnips and wheat, which did not need it.

MR. JOHN HUGHES agreed with the author that 2 per cent. citric acid was abnormal as an official test for phosphorus, and thought that as phosphates were likely to be used much more in the future, especially in the present year, owing to the scarcity of sulphuric acid, a much weaker solution of citric acid would be found very useful for testing the relative solubility of the different kinds of raw phosphates. With regard to the wonderful results produced by basic slag, he had come to the conclusion that they were due to the quantity of lime it contained in a very fine state of division. In ordinary slag there was from 18 to 19 per cent. of phosphoric acid, and perhaps from 40 to 45 per cent., or even 50 per cent., of lime which was in a particularly fine state of division. Further, in the samples that showed a high solubility in 2 per cent. citric acid, there was usually about 2 per cent. of caustic lime, which had a special and effective action. Some experiments were carried out a few years ago in Herefordshire by the Agricultural Organiser there, the results of which showed that finely-ground limestone, unburnt limestone but ground very fine, had a better effect than caustic lime, and he thought that supported his belief that the fineness of the grinding of the lime had a great deal to do with the success of basic slag. Now that basic slag was difficult to obtain, he thought farmers would be well advised to make greater use of lime in as fine a state of division as they could obtain it. It had been proved that some plants would take up lime in place of potash.

MR. W. A. COX thought the author should have referred to the use of basic slag in the case of root crops and potatoes, etc., in which connection it was very little inferior to superphosphates, as had been shown by experiments carried out by the Department of Agriculture in Ireland. With regard to the citric-acid solubility test, the results of experiments carried out during the last few years had shown clearly the superiority of high citric-acid soluble slags over slags of low solubility, but unfortunately those experiments had not yet been published. He did not mean to indicate, however, that there was no value in low soluble slag. Further, the results of experiments carried out in Germany, as Dr. Dyer had remarked, showed clearly that there was no reason whatever for departing from the citric solubility test. With regard to the Chairman's statement that the good effects of basic slag were due to the presence of free lime, he would like to remind him that in various parts of England and Scotland superphosphate *plus* ground lime in combination had been tested against basic slag alone, and without exception the results had been in favour of the basic slag. He wished to emphasise the point that basic slag had an excellent effect not only on grass land when applied in the autumn, but also on the root crops and the potato crops when applied at the time of drilling the seed and planting the tubers respectively.

MR. WALTER F. REID differed from previous speakers by holding that it was the soluble silica in basic slag that produced the good results on corn and other crops. When he was making Portland cement, the dust from the factory used to be blown over to certain areas of grass land, and in those places the grass always improved. There was no phosphoric acid at all in the Portland cement he was then making. He thought considerable quantities of basic slag could be obtained at the present time; a very large amount of steel was being made, and every ounce of steel meant a quantity of basic slag. There was not very much potash in this country, but there were deposits of it in Alsace superior even to those at Stassfurt, and if, as was to be hoped, Alsace reverted to France after the war, some of that supply would in all probability be available for this country. With regard to nitrates, the air around us contained the material to produce exactly what farmers wanted, and something was now being done in that direction. In 1906 he was a member of a deputation to Mr. Lloyd George, then at the head of the Board of Trade, with regard to the compulsory working of patents in this country, and he then said that it was quite useless to have a patent if the industry in connection with it was not to be established in this country, for then we should not produce the material required to keep the enemy from our doors. He wished to point out to the author that the bulk of the nitre-cake, supplies of which were available at the present moment, was made from the manufacture of nitric acid, and not in the way the author had indicated.

MR. ALFRED AKERS agreed entirely with the author as to the value of chemical manures. He had the greatest faith in superphosphate for wheat, and he was pleased to hear the author say that it should be put on in the autumn. During the war he had quadrupled his area of wheat, and he invariably put on a good dressing of superphosphates just before the wheat was drilled. With regard to the author's remark that a greater production of food in this country could not be obtained without the use of fertilisers of some kind, he ventured to say that one way by which the food production could be increased was by getting back a larger proportion of grass land into arable land. In Germany the land was something like two-thirds under the plough and one-third grass, whereas in this country it was just the other way about. Land which was under grass for a good many years accumulated a great quantity of humus and other things which constituted an admirable manure for either corn or root crops which might succeed the grass, and he did not agree that that land would require immediately any large quantity of chemical manure.

The two great difficulties were time and labour, but he thought it was of the utmost importance that more of the land in this country should be under the plough.

Mr. H. Trustram Eve thought farmers were inclined to use much more artificial manure at the present time than they used to do, but they were met with the difficulty of how to obtain it. They wanted to know whether they could get certain manures, and, if so, where—price was a secondary consideration. People frequently wrote to him asking those questions, and he advocated the establishment of a Bureau of Information to deal with them. Basic slag in large quantities would be required by farmers in the spring, in view of the increased quantity of food that was demanded from them. Labour in connection with basic slag had now been made a reserved occupation, but even so that industry was suffering from a great shortage of labour. He suggested that a leaflet might be issued saying exactly what could be done for the 1917 crop in the way of manures, and if the farmers could not be supplied with them they had better concentrate their attention on lime or soot; on some lands even salt was better than nothing. He did not think farmers ought to be blamed at the end of the year for not having used more manure, in view of the great difficulties they experienced in obtaining it.

Mr. A. E. Strong, as a manufacturer of fertilisers, said he was sorry he could not give any satisfactory answer to Mr. Trustram Eve's questions. The manufacturers themselves wanted to know whether they were going to have more phosphates, how much acid they were going to obtain, how long their present very much depleted labour staffs would be left to them, and so on. He thought farmers who were really alive to the necessity for fertilisers would have obtained them a month or two ago, and that any farmer who was now looking about for some superphosphate or basic slag would find he had to go without. Even so, however, a crop grown without manure would be better than none at all.

Dr. George McGowan said that there were very large stocks of nitre-cake and low-grade phosphates in this country, and he thought they ought to be utilised. With regard to potash, there were various sources from which that substance could be obtained, one being a green sand in a very fine state of division, and another the waste products from wool-scouring works in Bradford and elsewhere.

Mr. W. E. Oakden wished to ask the author whether it was absolutely necessary that the ammonia produced in gasworks should be converted into the sulphate. Could it not be utilised in some other form, and the sulphuric acid necessary to form the sulphate of ammonia be utilised for the purpose of producing the superphosphate?

Mr. George V. Parker said that, with regard to the remark of Dr. Dyer that very little was known in this country about the open-hearth process, there were at the present time only about four Bessemer furnaces in this country, the remainder being the open-hearth or basic processes; therefore he thought we knew a great deal about the open-hearth slag. There were firms in this country now willing to grind the low-grade basic slag, and they were only waiting for a little encouragement from the Board of Agriculture. When that was forthcoming they would go ahead, and there would be something like 180,000 to 200,000 tons of slag available in this country. He anticipated that next year there would be at least 150,000 tons of slag available for use here which were not available last year or in the previous year, owing to the Board of Agriculture having previously given licences for export to anyone who asked for them.

On the motion of the Chairman, a hearty vote of thanks was passed to the author for his very interesting paper.

Mr. J. A. Voelcker, in reply, said he was sure everyone realised that manure manufacturers had dealt loyally with the nation in the present time of crisis. He thought the various remarks that had been made about basic slag proved his contention that basic slag was a thing nobody as yet could understand. He was not satisfied that the results of experiments up to the present at all bore out the value that was attributed to the citric-solubility test. With regard to obtaining nitrogen from the atmosphere, this country ought long ago to have turned its attention to that subject. He thought the value of turning grass land into arable land depended very much on the kind of grass land that was converted. It was not likely that people would use their best grass land for that purpose—if they did they would not want good fertilisers; but with the poor kinds of grass land that would probably be used fertilisers would certainly be wanted. In reply to Mr. Oakden's question, it was certainly not necessary that gasworks ammonia should be made into sulphate of ammonia.

Mr. Mateo Clark writes:—I think it important that certain erroneous reports as to the approaching exhaustion of the nitrate supply should be contradicted. Surveys were made in various parts of Chile, and in 1911 it was ascertained that there existed 200 million tons of nitrate capable of being profitably extracted, and as the largest amount exported recently has been about 3 million tons per annum, at this rate there would be enough for about seventy years. These figures, it should be borne in mind, refer only to the last surveys made, but there are still very large tracts of the same class of ground not yet surveyed, and in the opinion of experts there is no reason why there should not exist in the country as good, or even better, beds of nitrate. These unexplored lands are of such extent that it is believed that at least four or five times more than the quantity so far ascertained

may exist for future extraction. It is therefore estimated that the supply of Chilean nitrate will not be exhausted for at least two hundred years, even at an increased rate of production. Improvements in the process for extracting the nitrate from the "caliche" are being introduced with the object of reducing the percentage of loss, which has hitherto been rather high.

EDUCATION IN TECHNICAL OPTICS.

A valuable report on this subject was lately issued by a committee* of the Board of Scientific Societies. The text of the report, which has been circulated, but not yet, we believe, otherwise published, will be found, with some introductory comment, in *Nature* of March 1st.

The report refers to the scheme put forward by the London County Council, but does not entirely agree with it, and, after pointing out the importance of a definite organisation of instruction and research in optics both as regards the needs of the optical industry and the requirements of Government departments, it proceeds to indicate the means by which such organisation could best be provided. Ultimately the Committee look forward to "the establishment of an optical institute which would concentrate the efforts of all who are concerned with the manufacture or use of optical instruments. It would bring together the several optical societies, which might find a home within its building; it would be the centre for the co-operation of the trade with students and teachers; it should contain a library with periodicals and books on optics."

The general direction of the courses of study would be invested in an advisory council on which the trade, as well as the optical and learned societies, would be represented. There should be a principal or director qualified on both the theoretical and the practical side. Full courses of instruction, in both day and evening classes, will be required.

The work would be adapted to the requirements :—

1. Of students engaged in the trade.
2. Of advanced students.
3. Of other persons interested in learning the scientific construction or use of optical instruments.

Provision should be made for research work not requiring a highly specialised or expensive plant. Special investigations might be referred to the National Physical Laboratory, or any other laboratory suitable for the purpose.

Inasmuch as it would probably be a considerable time before so complete an institution could be organised, the committee conclude their report by a summary of the requirements which appear to them to require immediate attention :—

1. The appointment of a supervising representative council.
2. The appointment, under the proposed supervising council, of an administrating director, with special duties during the transitional period, which will include advice to the trade and the organisation of the different parts of the curriculum.
3. The translation of suitable works and the abstracting of other important publications on technical optics.
4. Pending the erection of a suitable building, the organisation of day and evening courses at the Northampton Institute, and arrangements for higher instruction at some other institution of university rank.

* Mr. Conrad Beck, Mr. F. J. Cheshire, Mr. E. B. Knobel, Sir Philip Magnus, Professor H. Jackson, and Professor A. Schuster (chairman).

ENGINEERING NOTES.

The Panama Canal.—The channel in the cut, says the *Panama Canal Record*, is in better condition now than ever before. The central cut through which the vessels pass, known as the sailing channel, has a minimum depth of 33 ft., and the least width of a channel of 30 ft. depth is 180 ft. This is opposite the rock known as "Gibraltar," at the foot of the East Culebra slide. This rock extends into the channel about 110 ft. from the prism line, for a distance of about 220 ft. along the axis of the canal, from station 1792 to 1794. At other parts, between the Culebra slide and at Cucaracha slide, the channel has been dredged to at least 30 ft. for the full width of 300 ft. between the prism lines. The dredgers Corozal and Paraiso are at work in the slide area. They are working close to "Gibraltar," removing the rock itself and cutting in behind it to prevent its being pushed forward. A number of drills are engaged every day, including Sundays, on the work of drilling and blasting the rock for the dredgers to remove it. It has been considerably reduced in size, and now extends only about 30 ft. above the surface of the water in the cut. The smaller dredgers have been withdrawn, because only a few can work to advantage in the area to which dredging is now confined, and the large dredgers can operate less expensively. Recent events seem to show additional reasons for the American Navy to make the interoceanic traffic as easy as possible.

The Channel Tunnel.—This tunnel, for which many schemes have been discussed by the Royal Society of Arts, now appears in a new light in reference to the present war. Sir Francis Fox, M.Inst.C.E., of the firm of the engineers who have prepared plans for the work, makes some interesting remarks in an article contributed to the *Revue Franco-Étrangère*. In this he says: "It is hardly necessary to call attention to the enormous value of such a tunnel had it existed during the two years of this great war. It defies all calculation as to what the saving in

suffering and in cost would have been. Every soldier, every horse, every pound of ammunition, all the guns, the vehicles, and nearly all the food have had to be carried across the Channel at prodigious expense. The armies of labourers in the docks of both countries, the long lines of ships carrying and discharging horses, timber, petrol, fodder, coal, coke, and rations, would not have been required. The military gain of being able to transport, without change, troops from our great camps, material of war from our factories, and to bring back the sick and wounded with the minimum of suffering and fatigue, would have been beyond all measure, while the release of our Navy from the arduous task of protecting the Channel waterway would have represented a saving probably of scores of millions sterling. It is, therefore, quite safe to say that the entire cost of the tunnel—£16,000,000—would have been paid for over and over again." However, according to the isolation theory of partisans and to some of the military advisors on the subject, the strange corollary inevitably follows, that if the suppositious tunnel had been constructed before the war took place it should be demolished on the declaration of peace.

Sun-power in Africa.—In a somewhat optimistic address on the coal resources of the United Kingdom, delivered recently at Cardiff by Professor Arnold Lupton, he included, though wide of the immediate subject of the paper, the matter of sun-power. He said that sun steam-engines have now been made on a practical scale, and one of fifty horse-power has been erected in Egypt at Maedi, near the River Nile, not far from Cairo, for the purpose of pumping water for irrigation. In these works there is considerable concentration of the sun's rays by reflectors, and the steam is used at a pressure only slightly above that of the atmosphere. Of course, with a low-pressure engine it is necessary to have a very good vacuum, and therefore a good supply of cold water for condensation. It therefore follows that, if the sun's power is used for heating steam boilers, these must be in some situation where it is possible to obtain a large supply of cold water for condensation at a moderate cost, and therefore, if a large power is required, they must be not too far from some great river or large lake or the sea. Owing to the low pressure at which the steam is used, there need not be much escape of steam, and consequently the loss of water need not be very large. Mr. Lupton continued: "There are, however, enormous areas of sun-burnt desert in Asia, Africa, America and Australia where the mighty power of the sun is in evidence almost every day, where sufficient condensing water could be obtained at a moderate expense over many millions of square miles." Although steam has been already generated by sun-power at Meadi at a speed equivalent to 200 b.h.p. per acre, and although if there were a large demand for sun-power boilers no doubt they would be greatly improved still, Mr. Lupton has taken the average power all the year round in the country between Cairo and Khartoum as being, say, 50 b.h.p. per acre. At that rate 1,000,000,000 b.h.p. could be generated from 20,000,000 acres, or, say, 30,000 square miles; so that it is not likely that the human race will ever require 1 per cent. of the available sun-power. It must, however, be borne in mind that the area of land immediately under the equator is comparatively small, and that there is considerable rainfall in that area. The dry places are from 20 to 30 degrees from the equator, and therefore the sun-power on any particular boiler will vary greatly with the seasons. But if the sun-power is in the Sahara Desert, what use is that to the people of the United Kingdom? The answer is that this power can be transmitted electrically at a very moderate cost, as may be shown. The professor then goes into the necessary calculations and data, which amount to this result—the cost would be, from the Sahara Desert to the United Kingdom, including interest on capital and working expenses, 0·36 of a penny per kilowatt hour. The cable carrying the power would deliver current in Spain and France on the way, and this would reduce the average length of the circuit.

The Marconi Vacuum Ampere Gauge.—The demand for a small, sensitive, robust instrument suitable for use equally on alternating and continuous current is not new, and inventors have made many attempts to satisfy it. It has remained, however, for the Marconi Company to produce just what is required, and a great demand for the new gauge is anticipated. The instrument is designed primarily as a maximum current gauge to indicate the condition of syntony in wireless circuits, and may be employed as a substitute for a thermo-junction and galvanometer combination in the measurement of wave-lengths and decrement. The principle involved is that of the bifilar suspension, one pair of the filament ends being fixed, and the other pair attached to a pivoted arm, the rotation of which is controlled by a spring acting against the tension of the filaments. When a current passes through the filaments, heating them and causing them to elongate, the arm takes up a new position, and the angular displacement as indicated on the scale is a measurement of the current. The movement is enclosed in a glass bulb exhausted of air. The sensitiveness is thus greatly increased, and the movement protected against damage and preserved from dust or corrosion. Readers who are acquainted with practical wireless work will realise that the instruments are likely to prove of the greatest service, not only in radiotele-

graphy, but in all practical application of electricity. The above particulars have been abridged from an article in *Wireless World* for February, in which the illustrations supplied afford much information of a detailed kind.

OBITUARY.

JOHN HOUGHTON MAURICE BONNOR.—Information has been received of the death of Mr. John Houghton Maurice Bonnor, which took place in New York on January 29th. Mr. Bonnor went to Ottawa last year to carry out the internal and external decorations of the new Parliament House.

He was born in 1875, and educated at a private school in Rhyl. For some time he worked in the office of Messrs. Young and Hall, architects, and subsequently in the architect's office of the London County Council. He then started as a craftsman, at first with the Artificers' Guild, and afterwards in his own workshop. He was an artist of much versatility, and worked in a great variety of materials, including jewels, metals, enamels, stained glass, mosaic, sculpture, and wood. At one time he held a class for jewellery at Camberwell School of Arts, and latterly at the Central School.

His work was well known and admired by a large and increasing circle, and his early death has cut short a career of unusually brilliant promise. Amongst his most important productions may be mentioned the stained glass heraldic panels at Balliol College, Oxford, and Caius College, Cambridge; the stained glass window in the church of St. Michael and All Angels, Turnham Green; the figures of Christ, St. Mary and St. John at St. Mary's Church Bermondsey; the large rood-beam in carved wood at St. Joseph's Church, Aldershot; a number of memorial tablets, pieces of church furniture, caskets, jewellery, etc.

He was elected a member of the Royal Society of Arts in 1906.

GENERAL NOTE.

HYDRO-ELECTRIC POWER IN CANADA.—Hydroelectric power has played a most important part in the industrial development of Canada. Within the Dominion, excluding the North-West Territories, practically all of the Yukon, and the northern and eastern portions of Quebec, it is estimated that nearly 17,750,000 h.p. are available. The actually developed power, whether for electrical production, pulp-grinders, milling or the many other uses, aggregates 1,712,193 h.p. Of this the highest figure is in Ontario, 789,466 h.p.; Quebec comes second with 520,000 h.p.; and British Columbia third with 265,345 h.p. Practically the whole of this power has been developed within the last twenty years, while about two-thirds of the total has been produced in the last decade.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 21.—G. W. JONES, "Colour Printing, and some Recent Developments." CARMICHAEL THOMAS, Chairman of the *Graphic* and *Daily Graphic*, will preside.

APRIL 18. — HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

APRIL 25.—SIR FRANCIS FOX, M.Inst.C.E., "Flour and Bread." CAPTAIN CHARLES BATHURST, M.P., Parliamentary Secretary, Ministry of Food, will preside.

MAY 2.—J. C. SHENSTONE, F.L.S., M.P.S., "Herb-growing in the British Empire: its Past, Present, and Future."

MAY 9.—PROFESSOR WILLIAM RIPPER, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

INDIAN SECTION.

At 4.30 p.m.:—

TUESDAY, MARCH 27. — SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India."

THURSDAY, APRIL 19.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

Date to be announced later:—

D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

Dates to be hereafter announced:—

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

JOSEPH PENNELL, "The Artistic Aspects of War Work."

Aldred Lecture.

Monday afternoon, at 4.30 p.m. :—

Lawrence Weaver, F.S.A., "Memorials and Monuments." Three Lectures.

Syllabus.

Lecture III.—March 19.—Equestrian figures—Group memorials—Public school, regimental and civic monuments—The War memorial—Teuton *versus* Latin spirit in design—The Christ of the Andes — Columns and arches — Buildings and bridges—Monumental art and town planning.

Howard Lectures.

Monday afternoons, at 4 p.m. :—

William George Fearnsides, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies." Two Lectures. (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market.

April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 19...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Aldred Lecture.) Mr. L. Weaver, "Memorials and Monuments." (Lecture III.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. General Sir Charles Warren, "The Significance of the Geography of Palestine."

Bibliographical Society, 10, Hanover-square, W., 5 p.m. Dr. E. Gosse, "The Posthumous Writings of Swinburne."

Geographical Society, Burlington-gardens, W., 5.30 p.m. Dr. E. W. G. Masterman, "Palestine: its Resources and Suitability for Colonisation."

Tuesday, March 20...Statistical Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.15 p.m. The Earl of Dunraven, "How to Improve our Fishing Industries."

Petroleum Technologists, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Dr. F. Mollwo Perkin, "Sulphur in Petroleum Oils."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. W. Gregory, "Geological War Problems." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. E. M. Lacey, "The New Electric Power-house at Birchills, Walsall."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Dr. C. A. Swan and Mr. A. Coburn, "Colour-Sensitive Plates."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. E. P. Allis, Jun., "The Prechordal Portion of the Chondrocranium of *Chimæra colliei.*" 2. Mr. D. M. S. Watson, "A Sketch-classification of the Pre-Jurassic Tetrapod Vertebrates."

Wednesday, March 21...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Mr. G. W. Jones, "Colour Printing and Some Recent Developments."

Aeronautical Society of Great Britain, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. H. Thomas, "Commercial Aeronautics."

Meteorological Society, Caxton Hall, Westminster, S.W., 5 p.m. Major G. I. Taylor, "The Formation of Mist and Fog."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor Sir Thomas Oliver, "The Hygiene of Occupation in War Time."

Microscopical Society, 20, Hanover-square, W., 8 p.m. Mr. K. Goadby, "Bacteriology of War Wounds."

Electrical Engineers, Institution of (Local Section.) 17, Albert-square, Manchester, 7 p.m. Mr. L. Leighton, "Equipment of Hull Joint Docks."

(Yorkshire Local Section.) Philosophical Hall, Leeds, 7 p.m. Mr. G. A. Juhlin, "The Voltage Regulation of Rotary Converters."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor W. L. Courtney, "Mr. Thomas Hardy and Æschylus."

Metals, Institute of, at the Chemical Society, Burlington House, W., 8 p.m. Annual General Meeting. 1. Mr. O. W. Ellis, (*a*) "The General Properties of Stampings and Chill Castings in Brass of Approximately 60/40 Composition"; (*b*) "Machining Properties of Brass." 2. Mr. S. W. Smith, "Surface Tension and Cohesion in Metals and Alloys." 3. Dr. R. Seligman, "Aluminium Production by Electrolysis: A Note on the Mechanism of the Reaction." 4. Dr. F. C. Thompson, "Annealing of Nickel Silver." (Part II.)

Thursday, March 22...Geographical Society, Kensington-gore, S.W., 5 p.m. Dr. J. Ball, "Modern Methods of Finding the Latitude with a Theodolite."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Metals, Institute of, at the Chemical Society, Burlington House, W., 4.30 p.m. Annual Meeting (continued). (1) Mr. W. J. Hocking, "Metal Melting as Practised at the Royal Mint." (2) Mr. G. B. Brook, "Coal Gas as a Fuel for the Melting of Non-ferrous Alloys." (3) Mr. C. M. Walter, "High Pressure Gas Melting." (4) Messrs. H. M. Thornton and H. Hartley, "Contribution to Metal Melting Discussion." (5) Drs. H. C. Greenwood and R. S. Hutton, "An Electric Resistance Furnace for Melting in Crucibles." (6) Mr. C. Hering, "Ideals and Limitations in the Melting of Non-ferrous Metals." (7) Mr. H. S. Primrose, "Metal Melting in a Simple Crude Oil Furnace."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. A. Fleming, "Modern Improvements in Telegraphy and Telephony. Lecture I.—Telegraphy."

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. H. Garrison, "New Zealand: the Wonderland of the World."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. F. R. McBerty, "Machine Switching Telephone Gear."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. W. Cleaver, "The Rational Design of Reinforced Concrete Wharves and Jetties, with particular reference to those for Wet Docks having a permanent Water Level."

City of London College, White-street, Moorfields, E.C., 5.30 p.m. Mr. C. J. Tabor, "Some Notes of the Damage to which Refrigerated Foods are liable."

Ladies' Alpine Club, 23, Savile-row, W., 8.15 p.m.

Friday, March 23...Royal Institution, Albemarle-street, W., 5.30 p.m. Mr. E. Clodd, "Magic in Names."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, March 24...Royal Institution, Albemarle-street, W., 3 p.m. Mr. S. Graham, "Russian Idealism—The Russian Madonna." (Lecture I.)

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 16, 1917.

Journal of the Royal Society of Arts.

No. 3,357. VOL. LXV.

FRIDAY, MARCH 23, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

TUESDAY, MARCH 27th, at 5 p.m. (Indian Section.) SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India." Owing to the absence of the author in India, the paper will be read by Surgeon-General Sir R. Havelock Charles, G.C.V.O., M.D., F.R.C.S.I., President, Medical Board, India Office. The RIGHT HON. AUSTEN CHAMBERLAIN, M.P., Secretary of State for India, will preside.

ALDRED LECTURE.

On Monday afternoon, March 19th, Mr. LAWRENCE WEAVER, F.S.A., delivered the third and final lecture of his course on "Memorials and Monuments."

On the motion of the CHAIRMAN (Mr. Alan S. Cole, C.B.) a vote of thanks was accorded to Mr. Weaver for his interesting course.

The lectures will be published in the *Journal* during the Summer recess.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

WEDNESDAY, MARCH 21st, 1917; CARMICHAEL THOMAS, Chairman of the *Graphic* and *Daily Graphic*, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Chatterjee, Atul Chandra, I.C.S., 15, Eaton Rise, Ealing, W. (5)

Watson, Ralph Douglas, 12, Tankerville-terrace, Newcastle-on-Tyne.

The following candidate was balloted for and duly elected a Fellow of the Society:—

Ledgard, Sir Henry, Langdale, Farnham, Surrey.

The paper read was—

COLOUR PRINTING, AND SOME RECENT DEVELOPMENTS.

By G. W. JONES.

When the Royal Society of Arts did me the honour of asking me to read a paper on colour printing by what is known as the three-colour process, I pleaded that the ground had already been so well covered by students, workers, and technical writers, that I should be in danger of finding myself in the position of Canning's knife-grinder, who had "no story to tell."

It was suggested, however, that I should treat the subject from the point of view of personal contact with the process from about 1893—first in experimental work, and subsequently in the commercial production of large quantities of colour printing. The desire was expressed that I should give some account of my experimental work in connection with the "Renaissance" method of intaglio offset printing, and it was more than hinted that I ought to be able to offer an opinion on how best to combat the Continental competition from which British colour printers by various methods have suffered in the past. In short, I was confronted with the task of reviewing from the national standpoint an important branch of my own particular industry, and of setting forth briefly my opinions on colour printing after the war.

An audience such as this, more or less intimately acquainted with photo-engraving and printing processes, will not require at my hands lengthy historical details of the rise and progress of three-colour printing in the British Isles. As practical men themselves, my hearers will naturally expect me to present them with the facts of practical experience rather than theories and historical generalities; yet, for the sake of lucidity, I find myself obliged to resort in the first place to the narrative form.

Colour printing from photo-engraved blocks,

as now and for the past twenty years in general use, was rendered possible about 1885–86 by the introduction of the cross-lined half-tone screen. It cannot be stated with certainty who produced the first English three-colour print issued commercially, but the honour is claimed on behalf of Messrs. Waterlow and Sons, who, in February, 1892, produced, as a supplement to *Land and Water*, a plate representing the Derby winner of 1890. By the courtesy of Mr. R. A. Peddie, librarian of the St. Bride Foundation Typographical Library, I am permitted to show this picture, with the progressive workings. It was produced under the superintendence of Mr. J. D. Geddes, a well-known practical photo-engraver, and a competent authority on the method.

The first supplement by the process to appear in the *British Printer*—a still-life subject—is to be found in the September-October number of 1893. The blocks were made by Husnik and Hausler, of Prague. About the same time supplements printed from chromotype blocks followed in quick succession—for British process-engravers applied themselves with zeal to colour reproduction—but no other specimen by the three-colour process appeared in the *British Printer* until the autumn of 1894, when a reproduction from a xylographic woodcut—evidently by the Knöflers, of Vienna—and its progressive workings were shown.

Aided by improved methods and more perfect filters, engravers at last touched the solid ground of the scientific process of photographic reproduction. Their efforts were heartily seconded by enterprising printers, who welcomed three-colour work as a new avenue of employment, and hastened to provide themselves with the requisite plant.

For a long time, I fear, the colour engraver was looked upon as the poor relation of the printing family. Twenty years of praiseworthy enterprise have placed him in the position of an equal. So certain does he feel his position to-day that his ability to make conditions is the envy of his printer colleague.

My own practical connection with the process began in 1892, when the late Mr. John Swain, jun., of the celebrated engraving house—for whom I had produced much half-tone printing—provided me with colour blocks for experimental purposes. We worked in collaboration for a time, and two of our earliest efforts are exhibited here.

Afterwards I printed "War Impressions," by Messrs. A. & C. Black, of Soho Square—the first book to be illustrated by the three-colour method—which appeared in 1903.

"Nice customs curtsy to great kings," and surely those who complain most loudly about "the mark of the beast" in the screen dot, and lament the inartistic appearance of colour work on coated paper, may forgive much to a levelling process like three-colour, which places the humblest almost on an equality with the rich in the matter of reproductive art. One might imagine that these grumblers object to art being "commercialised," as they style it, not because commercial art is vulgar, but because it is cheap.

The three-colour method is in general use, not only for colour reproduction of pictures and drawings, but also by the commercial world for the illustration of natural products and of manufactures of almost every kind. Science has followed suit, and it would be difficult to specify any form of human endeavour depending for success upon truthful colour presentation which has not benefited by this important development of letterpress printing.

The conductors of the best illustrated newspapers, who have moderated their enthusiasm since the outbreak of war, were among the greatest fosterers of three-colour printing for the brightening of their pages, while many of their most progressive advertising clients resorted to its use for more effective advertisement. It may here be remarked in parenthesis that the recent issues of the principal illustrated weekly newspapers published by our chief enemy show no diminution in the amount of colour work they contain.

If the three-colour process is not yet considered an essential trade or calling, it has woven itself into the web of our commercial life.

Probably every member of my audience will agree with the Ruskinian dictum that "every rightly-constituted man loves colour." To attempt to question it would be equal to "speaking disrespectfully of the Equator." But even the most enthusiastic must allow for difference of opinion, and it may be conceded without a murmur that, unless the colour be good, black or monochrome is preferable. When colour is good and justifiable, it is because it is a faithful reproduction of the original. When it is bad, it is a crime—for the double reason that it is an offence by the perpetrator and a degradation of the original.

It may be mentioned here that surface-coated papers, suitable for receiving and retaining the nicest shades of the photo-engraved plate, had previously been supplied to meet the demands of half-tone monochrome printing.

These required little adaptation for colour blocks by the same method of engraving, and from the printer's point of view met the case more or less completely; but readers justly objected to the weight of the coated paper, to the feeling of repulsion which it induces on touch, and to its liability to adhesion from contact with moisture.

The best results in printing from half-tone blocks, whether in one or more colours, are obtained by the use of a press combining rigidity of impression and perfect rolling power. The ideal impression is that of firm contact, just sufficient to lift the ink from the plates, and not squeeze or extreme pressure, which is fatal to good work. The demand for improved presses to print the heavy woodcut work previously used freely in American catalogues and similar productions had been responded to by American press manufacturers; and for the purposes of the new half-tone printing, British printers gladly availed themselves of platen and cylinder machines imported from the United States. They were thus enabled to grapple with the three-colour process fortified by experience in the make-ready and printing of half-tone blocks on specially-designed presses which possessed in addition the necessary advantage of accurate register. English machine manufacturers were not at this time quite awake to the needs of the hour, but when they realised the possibilities of the new development they endeavoured to rise to the occasion, and many improved machines were turned out. I may return to this subject later.

The three-colour block thus found the clay-coated paper, the heavy platen press, and the two-revolution machine ready for its advent. To render it a commercial success suitable inks and competent workmen were also necessary.

Taking first the matter of coloured printing inks, it is common knowledge that, when the new process was introduced, Germany supplied a great part of the dry colours used by British printing-ink makers, as well as a large amount mixed ready for use, which went direct to the printer.

The British printing-ink manufacturer was as keen as the engraver and the printer to appreciate the importance of the new printing method, and the demands it was likely to make on his resources; and if to-day, when free access to the principal source of supply of the raw material is closed to him, we are experiencing but a moderate amount of difficulty in meeting our requirements, it is owing to the grit and grip with which, against great odds, the home manufacturer has contended for a considerable number of years.

His position was pretty well as unenviable as that of the British printer. The latter had to meet a competition as unfair as it was insidious and persistent. He was practically obliged to go to Germany or America for one build of press, as well as for much of his coloured inks in their manufactured state, and was required to quote against scientifically equipped German competitors, who were paying only some 75 per cent. of the wages paid in England for a similar output of work. The British printing-ink manufacturer at the same time was dependent largely on the German manufacturer for his dry colours. Some of the German printing-ink manufacturers employ in their laboratories colour chemists of European reputation, with a considerable number of assistants, who are able to devote all their time and accomplishments to research and experimental work without the distraction of the commercial side of the business.

Surely if any process of manufacture requires the utmost aid of science, the production of coloured printing inks calls for the employment of skilled chemists possessing a special knowledge of the testing of pigments in all their phases as to their suitability for this manufacture, as well as skill in the mixture of the pigments with the vehicle and other ingredients which go to make printing inks suitable for the finest colour work.

Too much, if we may judge from experience, has been left to the foreigner in this most important department. The business is sufficiently large and important to justify the assistance of the best scientific chemists that this country can produce.

If the aniline dye industry can be reconstituted in England, there is reason to hope for the future independence of ink maker and printer in this particular.

As to the printing machineman, the last link in the chain of production, the younger workmen of the British machine-rooms responded readily to the new demand on their patience, skill and thoughtfulness, and, given proper facilities and conditions, proved themselves able to hold their own with Continental competitors.

A good eye for colour is as essential to a printing machineman as careful make-ready and exactness of register. Another requisite is that the printing machineman should, if possible, be allowed to specialise in colour work. If it can be avoided, it is undesirable to give men alternating formes of black and colour. The

minder, on his part, can do much to qualify for specialising by the study of colour both in nature and in art. The best engraved block may be rendered nugatory if treated unsympathetically in the machine-room.

Controversy has always raged as to whether three or four blocks give the best result in colour-printing, *i.e.* as a general principle, especially because purer primary colours may be used. Were the system to be standardised one would unquestionably favour the four printings. This judgment is justified by the practice in the United States, France, and Germany. In Great Britain, however, the printer's preference is too often hindered by considerations of price, and four-colour workings are less often resorted to than three.

There are, perhaps, instances in which the three colours give the better, or perhaps the most transparent, result.

By the kindness of Messrs. A. & C. Black I am permitted to show progressive workings and finished print from a set of small three-colour blocks of "The Bird's Nest," photographed direct from the original drawing by Birket Foster.

The reproduction is exactly the same size as the drawing. The blocks were made at Watford under my direction. In this case I am of the opinion that an additional block would not have improved the picture.

About the same time Messrs. Black wished me to produce three-colour blocks for the printing of some threescore Morland pictures. I could not admit that it was possible in this instance to obtain in three printings the high standard of colour-faithfulness desired. The matter was tested by the preparation of one set of three colour blocks, when it was demonstrated that four printings were necessary. In this case I did not find the use of the three primaries and black quite satisfactory, although theoretically they should have been the best to use. Finally, by proofing two sets of blocks in several different sets of colours, in the endeavour to get the strength and tone which is generally apparent in the paintings by that master, we arrived at a result which approximated closely to the pictures and proved satisfactory to all concerned. We used the same series of colours throughout, in order that a large number of plates could be printed together on one sheet.

In the large framed reproduction of "The Fortune Teller," by Morland, which is shown here, I have used a grey tint in addition to the four colours. The picture was photographed direct from the original in the National Gallery. The other three Gallery pictures—"The Infant Samuel," Turner's "Venice," and Mrs. Robinson ("Perdita") after Romney—were all reproduced direct and printed in four colours. In each case, except that of the portrait of Mrs. Robinson, which was inaccessible, several visits were made to the Gallery for the purpose of comparison with the subject, in order to ensure fidelity to the colour of the original picture.

The four Thorburn reproductions, and those of motor-cars and dental chairs, were all produced by the four-colour method.

In the case of the Oriental china prints, one extra green plate was made for the Famille-Verte vase plates; and an extra blue was used in the plate showing a pair of blue vases. These plates were reproduced direct from the original china ware in their London home.

The large sheets, showing the progressive workings of a sheet of book illustrations, are exhibited to show that no insuperable difficulty is found in printing a sheet of comparatively large size containing a number of blocks.

I trust the work by this process will be deemed sufficiently representative to demonstrate the wide applicability of this simple and natural method of printing from photo-engraved blocks, and the universality of its usefulness.

Perhaps it is fitting that I should state here that that usefulness has been enormously advanced by the ability of the printer to procure duplicate plates from his original engraved blocks — duplicates so faithful in all printing respects to the half-tones that, when printed with the original plates, it is impossible even for the skilled printer to distinguish them with any degree of certainty.

The great improvement in the manufacture of printers' rollers, both in composition of materials and method of casting, has helped materially in making this method of printing a thoroughly commercial one.

One imperfect roller may mean ruin to the perfect printing of a colour job which, in the various manufactures and operations which go to the complete work, may have called for the co-operation of hundreds of workers.

I have referred generally to the principal necessities of the colour printer (if he is to produce work of excellence), such as the press or machine, the paper generally used, inks and rollers. The many other accessories and lesser necessities vary according to the nature of the

work. Such an apparently simple matter as interleaving paper calls for great care in its selection. Prime considerations, however, are those of heating and lighting. All other conditions may be perfect, but without good lighting, and especially the ability to maintain a sufficient and even temperature, you will be dogged with difficulties.

The half-tone method of illustration has much to answer for as the principal agent in the displacement of wood-engraving, which for centuries was the chief method employed for book illustration, and for years immediately previous to the advent of the photo-mechanical process had been very extensively used for commercial purposes. Many lovers of the beautiful handicraft still cherish resentment towards the photo-engraver. A like feeling has called forth expressions uncomplimentary towards the workers and advocates of three-colour printing. With its advent the days of chromo-xylography were numbered, but few tears were shed over its funeral.

It cannot be hoped that the atmosphere and opportunities of the engraving departments called into being by the new means of colour reproductions will be fruitful in the production of artists of great ability, such as have graduated from the engraver's studio and the lithographic shop. Many instances of such inspirations and encouragements are recorded. The painter of delightful English country scenes and English children, a reproduction of whose sweet little drawing of "The Bird's Nest" is in your hands, was a wood-engraver before he became a painter. There were many others.

But another beautiful handicraft that fell to be adversely influenced, as the new method became perfected and more widely adopted, was that of chromo-lithography, and soon a large proportion of the work left to be produced in these islands began to be printed by three and four colours by the letterpress method.

And this was not a consummation devoutly to be desired. True, for much of the best lithography British consumers were going to Germany, notwithstanding that that country has never turned out by the art-craft of chromo-lithography work more excellent than that produced by, to go no further, Messrs. Griggs, of Peckham, and Messrs. Vincent Brooks, Day & Son, who have a proud record, and Messrs. M'Lagan & Cumming, of Edinburgh. If I mention these names it is by reason of the high character of their work over a long period, and the possession of an indomitable resolution which has enabled them to put up a good fight against a competitor so well equipped and privileged. The chromo-lithographer still has a field of work which the three-colour printer can never occupy so successfully; and it is well the colour printer should recognise this. Some of the greatest failures of the letterpress colour printer have been made by attempting work which is better left to the older method of printing.

Although the newer method has had a disturbing influence on the—if I may so term them—more human crafts I have referred to because of its mechanical foundation, the processes of engraving and printing demand in both departments unceasing watchfulness and care, as well as the highest application of skill and knowledge. The human element is essential in the last degree. The workers need to be always at concert pitch, their vigilance must be unceasing. Relaxation means with certainty a spoilt negative or plate; in the printing machine-room, deterioration of result.

Each original picture or object will be found to differ from its fellow, and call for more or less individual treatment in the studio and etching-room. In like manner the printer usually also finds plenty of play for his mentality, so that if the method has displaced one set of human activities it has brought others into play.

May I, speaking as a printer, make another reference to the colour-engraver's task? I need not here dilate on the necessity for harmonious working in each department; it is somewhat repugnant to the British spirit to be asked to consider another man's job and difficulties. The engraving staff must work together like a well-trained football team, each ready to play into the hands of the other.

Careful lighting of the object, the correct exposure, equally careful printing on the copper, and nice judgment in the etching of the plate, to say nothing of the proofer's work, are all demanded. When all receive their due attention there is little work left for the fine-etcher—who should be, as far as possible, the unobtrusive human element in a scientific process.

One of the greatest failures recorded in the history of colour printing in this country resulted from half a dozen men going their own way instead of considering the possibilities and limitations of the other departments. They all wanted to row stroke oar, and the boat scarcely got off the mark.

Many years ago I took a proof from a roughly-etched set of colour plates to the studio of a well-known R.A.—he is at the moment president

of a Royal Society—in order that notes might be taken before the fine-etcher commenced his work. The picture had been photographed at the artist's residence. To my surprise he suggested that it might be printed as it then appeared. It gave his drawing. He overlooked unfaithfulness to colour rendering of the original, because there was an utter absence of the retoucher's handiwork.

In the case of pictures of merit, especially, the greatest care should be observed—although the rule applies generally—not to over-etch a plate. I think over-etching is the most fruitful cause of trouble in true colour reproduction. It springs largely from the Britisher's readiness to take a risk. The most skilled engraver or burnisher, working on a multitude of dots of varying strength, can never give back that which he has allowed the bath, by imperfect judgment, to eliminate.

As one who has suffered long and much from the result of over-etching, I should say that more money has been wasted in the endeavour to patch-up —it is nothing else—plates so treated, with its additional waste of time and money in reproofing, than would have paid for the remaking of the plates twice over.

I have referred somewhat at length, if lightly and generally, to the engraving side of colour printing, in order not only that I may call attention to their difficulties, but also pay my tribute to the excellent work of a large body of craftsmen who are often called upon to work miracles in the matter of time, and to achieve the impossible by reproducing work which might have been painted by someone who had a big grudge against the method. Especially I wish to counteract the notion possessed by many people that the photo-engraver simply presses a button and rocks an etching-bath. The printer whose work it is to collaborate with the engraver should form a just estimate of the demands on his colleague's judgment and skill.

I have spoken of the dependence of the colour printer on the ink manufacturer, and given expression to the hope that colour chemists of eminence may, in the near future, be persuaded to devote some of their scientific knowledge and abilities to the industry. I may also here point out that the printer's reliance on the paper manufacturer is almost absolute. The printer daily brings his experience to bear on the treatment of his coloured inks, but a badly-made paper will defy all the resources of his skill and experience. A paper may be kept in a machine-room of even suitable temperature for two or three weeks, and still give endless trouble, unless the "body" of the paper was well matured before receiving its coating, and due time was allowed to elapse before finishing. I remember an instance of a printed sheet, 36 in. wide, showing, after momentary exposure to the atmosphere, a variation of nearly one-eighth of an inch on being immediately run through the machine again.

It is to be regretted that a substitute for coated paper has not been found, which shall give equal printed results from the half-tone colour blocks with the same ease and certitude. The best effect of the half-tone, with all its variations of light and shade, are—as in the early days of the process—got on the sympathetic art paper, and the indefinite or "fuzzy" appearance when printed on most calendered papers is accentuated when the impressions of three half-tones are superimposed.

Much really excellent colour printing, generally in four printings, is produced in the United States of America on non-coated papers of highly finished character. The fourth printing is essential to good result on such material. These papers have not "caught on" with home printers. They have the advantage, however, of less susceptibility to atmospheric conditions. Excepting in the more expensive kinds—wood being the principal ingredient—the colour soon deteriorates, so that they are unsuitable, as are clay-coated papers, for work intended to be of enduring usefulness. Unless the qualities of sharpness and beauty of impression are to be in considerable degree sacrificed, I fear the following criticism, directed against colour printing on coated papers, will long be pertinent: "It is now well understood that many of the beautiful and luxurious editions and periodicals published within the last few years, at an immense expenditure of time and work, will last but a short time. And it is most especially unfortunate that artistic inspiration, which has expressed itself in the illustration and composition and printing of such works, will not become a heritage of future generations."

"'Tis true, 'tis pity;
And pity 'tis, 'tis true."

British paper manufacturers have made gallant attempts to meet the objection just referred to. My own printing trials, at the request of papermakers, have been legion. Twelve or thirteen years ago Messrs. Joynson, the well-known writing-paper manufacturers of St. Mary Cray, and Messrs. John Dickinson & Co., at one of their Hertfordshire mills, were both

working assiduously, I believe unknown to each other, in the endeavour to produce a rag printing-paper, and so of great permanence, which could be used for the best class of three-colour illustration. The former firm, after exhaustive experiments and much cost, I believe, gave up further endeavour. Perhaps those present will be most interested if I refer specifically to my experience in printing an important series of illustrations on paper manufactured by the latter firm—Messrs. Dickinson—which they termed their "Rag impression." The late Mr. Thomas Barratt (of Messrs. A. & F. Pears, Ltd.), who supervised the preparation of his " Annals of Hampstead " for the press, determined that the whole of the paper to be used, both for the letterpress and illustrations, should be, as far as humanly possible, non-perishable. To this end he decided to use rag-impression paper.

The finished results obtained on this medium were, in many cases, entirely satisfactory; but, unfortunately, owing to the difficulty of securing regularity of evenness of finish—absolutely essential in a method dependent on " contact " of paper and block in contradistinction to " squeeze "—a considerable amount of waste occurred in printing the heavier subjects. It is greatly to be regretted that the manufacturers subsequently abandoned the production of this permanent substitute for the perishable coated material. I have, in addition to a number of smaller works, printed a series of quite large four-colour blocks on the rag paper for one of our largest advertisers, who, having spent considerable sums of money on original paintings, decided that the reproductions should be made on a permanent material. I show two sheets of plates for Mr. Barratt's book, all printed from four-colour blocks on rag-impression paper.

" The Bird's Nest " is shown printed on the same material and on coated paper in order to allow of comparison of results. The comparatively light and delicate nature of this subject renders it more suitable both for the three-colour process as opposed to four colours and for printing on non-coated paper, although it will be noticed that even this little subject loses in sharpness when printed on the latter.

At least four printings are required to get anything like successful results on such paper, especially if the subjects are strong and the blocks carry depth of colour.

I was about making further experiments in printing on paper of this kind, when unfortunately Messrs. Dickinson, owing to the difficulty of manufacture, dismantled the special machinery they had built and stopped further supplies.

I have stated that a leading principle of colour printing by the three- and four-colour process is contact instead of pressure. Another is the efficient cleaning of the plates after each impression, *i.e.* the blocks should deposit practically the whole of the colour on the paper at each impression. If the strength of impression is extreme the picture will be dulled by the spreading of the colour, which will also be forced into the extremely minute interstices separating the screen " dots." This, which makes not only for " fuzzy " but also dirty work, is an insuperable bar to the general use of the otherwise very desirable uncoated papers. Their necessarily imperfect surface demands heavy pressure for the purpose of receiving an equal distribution of colour on even and uneven parts.

I have referred to the sympathetic co-operation necessary in all departments of the photo-engraving house. The sympathetic co-operation of engraver and printer is a *sine qua non* in successful colour reproduction by mechanical processes. It is but fair to say here that, but for it, we could not have produced the large gallery pictures which I am permitted to exhibit in illustration, and I am happy to give expression publicly to grateful thanks for such co-operation and help. When a series of plates is imposed in one large forme—for the size of sheet that can be printed from three- or four-colour blocks is regulated only by the dimensions of the printing machine and the skill of the machine printer—the printer requires blocks which have been proofed by the engraver not only in the same shades of the primary colours, but also with the same strength of colour and the same amount all over the surface of the plate. At the moment we are printing for a photo-engraving firm a sheet containing fifteen or sixteen quite large blocks. Half a dozen of these had been proofed each with a different colour of blue ink—a very serious handicap to good printing. Quite recently we discovered that a large plate when proofed carried on the left-hand portion almost double the amount of colour used on the other. As we were called upon to print in duplicate, and therefore to roll in the reverse way to that in which the block had been proved, our task was not lightened. Some system of standardisation on the part of engravers might produce better results.

Hitherto I have confined myself to consideration of the ordinary method of printing the various colours separately, but machines have been invented for the simultaneous superimposition of colour, and although no great progress has been made by these in England, they at least deserve mention. Some few houses employ coupled-up presses which carry the sheet in one journey through its three impressions. In the opinion of many competent judges this method finds its best scope on long runs for which the highest class of result is not demanded. I have never found that the continuous run and the practically simultaneous printing of colours one over the other gives sufficient sharpness and beauty of result, and I have not been tempted to adopt this time-saving device. The method used by the Quadri-Colour Co., a United States house, produces much excellent work, but a strong family likeness pervades all its productions.

In production for commercial purposes speed is often vital, and here the three-colour process possesses obvious advantages. As one instance in point, I may be allowed to cite a personal experience. When the news of the death of Commander Scott, of the Antarctic Expedition, reached England, I was commissioned by the management of one of the London illustrated weekly newspapers to reproduce a coloured photograph of the hero's little son, Peter. The coloured photograph was received by me shortly after noon on Friday, and by the following Wednesday the large edition demanded was delivered, printed in three colours and plate-marked. What colour process can compete with this in celerity of production ?

A process capable of meeting so insistent a demand, as well as those more leisured—though it is to be feared that few leisured demands come the way of the printer—of discriminating art lovers, dealers and publishers, must of necessity be a powerful instrument in the hands of commercial men. To enumerate would be but to repeat the story of the all-embracing usefulness of this interesting means.

There is indeed no royal road to colour printing by this process. Every job brings its own little difficulty, and therein lies the charm of the process for the craftsman. In general terms I am an enthusiastic advocate of the standardisation of industries. Yet I hope that I may not live into an age when blocks, ink, paper, machines and men have been conformed to such an extent as to relieve the calling of its human element. Our very deficiencies and imperfections are among our best incentives to progress. A complicated and difficult subject calls forth the utmost efforts of studio and etching-room, and these are reinforced by vigilance and sympathetic treatment on the part of the printer. When the personal equation is rightly adjusted, material and mechanical obstacles which might otherwise appear insurmountable may often be overcome, or at the least rendered much less formidable, and the worker braced and better equipped to grapple with the next problem.

The Renaissance Method.

I now pass to my connection with the "Renaissance" machine, manufactured by Messrs. Linotype & Machinery, Ltd., to whom colour printers by relief and other methods are much indebted.

In illustration of the story I have the pleasure of submitting for the inspection of the audience several specimens of work done on the machine, all of which, with the exception of one printed at the Broadheath works of the company, were produced in my office in London.

The Renaissance method differs from ordinary intaglio photogravure in the respect that, instead of the subject being engraved direct on a copper cylinder, which, after being placed in position on the machine, has the surplus ink removed from it by a steel knife before coming in contact with the paper, the subject for printing by this process is etched on a flat sheet of copper, such as is used for an ordinary half-tone engraving. The "Renaissance" is a sheet-feed machine possessing two reciprocating cylinders, grooved to hold, by clamping, steel turtles on one of which is fastened the engraved copper plate, and on the other a sheet of rubber which receives the impression from it. This, in its turn, is transferred to paper, which, passing round a smaller cylinder, is pressed with due force to receive it.

The inking apparatus consists of a duct admirably controlled as to supply of ink, and three distributing and three inking rollers. After the plate has been inked, it travels to the wiping rollers, which are placed beneath the cylinder. It is there cleaned of all the ink not required before coming in contact with the rubber.

Thus, by an ingenious combination of intaglio (or photogravure) and offset methods, a print is obtained which embodies the outstanding properties of both processes. The photographic screen is very much less palpably in evidence than in direct intaglio photogravure, owing to

the almost imperceptible spreading of the colour when deposited on the paper.

Before going farther, it may be noted that one great advantage enjoyed by the "Renaissance" over ordinary photogravure is the fact that the Renaissance plates holding the engraving may be stored for future editions in the same way as ordinary half-tones, stereo and electro plates; while the intaglio method, pure and simple, implies, for the purpose of fresh editions, storage of the etched cylinders, which is quite impracticable, or the regrinding of the cylinder, a fresh deposit of copper and a re-etching. It was the practicability of retaining plates for future use that, among the advantages which the machine seemed to possess, appealed to me, as a practical printer, very strongly.

Let me make the interpolation that, with the exception of a very small job, all the specimens shown in illustration of the Renaissance method must be considered as first attempts, as purely experimental work.

To demonstrate then the commercial, and so the practical, character of the machine, I had a small medallion portrait of Dr. Johnson—from a stipple engraving by Bartolozzi—etched and printed for a cover for an 8vo booklet. Two or three months afterwards, a second edition being called for, the original plate was placed on the machine and printed as previously, an operation calling for only two or three hours' labour.

A very short experience with the machine satisfied me as to the exactness of register and complete control of ink supply. Being assured on these points, and also that the process afforded a sure means of printing by photo-engraved plates on uncoated paper, I determined at the outset to test it for colour printing. To save time, and as a ready means of demonstration, I procured a set of reversed half-tone three-colour blocks, which afforded some sort of cell for the reception of the colour to be deposited on the rubber. This test was carried out with the roughest of etching, the ordinary three-colour primary inks, and a miscellaneous assortment of paper. The result fully satisfied my expectations. A few hours sufficed to clean up the machine, get the plates in position, run up the colour, and take a few impressions. Until we got the second plate in position and an impression in its colour on the yellow ink, I really believe some of the experimenters thought they perceived the dawn of second childhood. It did not take long, however, to discover method in the madness.

The first plate printed in colour I have the pleasure of showing you.

The first experiments in colour gave no advantage, but the contrary, to coated paper, as might have been expected; but the results on some cheap interleaving paper I had provided for the purpose were as good, or nearly as good, as those on etching and similar papers of varying degrees of finish.

The machine was subsequently installed in my premises in Gough Square, where the reproduction of a water-colour drawing of the "Two Turks"—the first picture in colours engraved by the intaglio method and printed on the "Renaissance" machine—was produced; as were the other specimens which I have the pleasure of showing to-day, along with the progressive working proofs and the plates from which they were printed. I had plates of moderately large size made, as it was essential that proof should be given as to the possibility or otherwise of securing register with intaglio plates of considerable size. Afterwards plates were made for the Thorburn "Pheasant" print, in four printings. Two plates mentioned, and the plate containing the four Indian subjects (which I had etched together to demonstrate the feasibility of obtaining register when more subjects than one were desired on a plate), are so far the only plates produced in colour by this method.

Much of the beautiful chromo-lithographic work produced in London forty and more years ago owed its excellence to the fact that painters of eminence did not consider it derogatory to their dignity to work on the lithographic stone when their own pictures were the subject-matter, and often did much more than put the finishing touches to them. The artist cannot object to the material that can be used by this method for printing reproductions of his work, for the only difference with a coarse-grained paper is that of increased softness of result, due to slightly more spread of the colour when deposited by the rubber. With the working of the "Renaissance" method his individuality would be conserved by study of the simple method, and taking pattern by the work of painters of a past generation, the three or four positives would offer him every opportunity for a like assistance.

It may be accepted as an established fact that almost any make or grade of papers may be used for indirect intaglio printing. Bristol boards, etching papers of varying degrees of roughness, Whatman and other hand-mades are

specially suitable, whilst the poorest results are obtained by the use of the heavily-coated papers found almost indispensable in ordinary three-colour and half-tone printing, and super-calendered papers.

It should be borne in mind when considering the results of a few months' experimental work that none of it is considered at all perfect, that the plates were made nearly three years ago, that the engravers were busily occupied in perfecting their methods for direct intaglio printing from the cylinder at the time they gave me their help, and that the two methods call for different treatment in etching. I am glad to be able publicly to express my thanks for valuable assistance from Mr. E. H. Rudd and from the staff at Messrs. Lascelles, who etched the intaglio plates for me at considerable inconvenience to themselves, and to Messrs. Winstone and Messrs. Shuck and McLean, who also gave me most cheerful and valued help with inks and colours.

The two impressions in red, from stipple engravings, were made from very imperfect originals.

Much of the fine work which was apparent in the reproduction from a pencil drawing of the Italian view, when first put on the machine, has been lost by reason of taking a number of impressions without protecting the very delicate work by steel facing.

The large plate of Dr. Johnson examining the MS. of "The Vicar of Wakefield" is from a mezzotint engraving, and is printed on common interleaving paper.

Letterpress matter reproduces perfectly, and I would point, in proof of this, to the very minute lettering of the engraver's name under the small medallion of Dr. Johnson on the cover referred to previously.

I have made reference thus far to results obtained and advantages of the machine. I have avoided reference to difficulties, not because there are none, nor because they have not yet all been surmounted, but because in them I am unable to perceive natural difficulty.

As a printer still possessing a lively recollection of all the travail and loss and disappointment experienced in the first years of working the three-colour method, and still finding a plentiful crop of difficulty springing up in working the process, I think that as the result of first experiment the large plates in colour printed on the "Renaissance" machine are at least interesting.

Just previously to war breaking out I was visited by the gentleman controlling the largest photo-engraving establishment in the United States of America devoted to intaglio work, four-colour—he said they never made three-colour—and half-tone and line. He was more than interested. He remarked that it was, in his opinion, the solution of printing photo-engraved plates on other than coated papers, and that, had he the machine in one of his establishments, he would create a department for producing only colour plates for the machines, and that he would not allow one to go out as a finished product until the staff were able to produce perfect printing plates with the same certainty as they now enjoy in producing for the method in general use. If I have been unduly optimistic about the "Renaissance" machine I have erred in excellent company.

With the outbreak of war my experimental work came to an end. The engineers who designed the machine found a more pressing demand for their activities. The future of Renaissance printing, therefore, is in the lap of the gods.

DISCUSSION.

The Chairman (Mr. Carmichael Thomas), in opening the discussion, said he was sure all present had been very much interested in the paper that had just been read. Personally he had been especially interested in what the author had said about the three-colour *versus* the four-colour process. In that respect he thought a great deal depended upon the subject of the picture. For instance, a richly coloured Old Master could not be satisfactorily reproduced by the three-colour process; it seemed to need a neutral or black tone, preferably the former. Certain subjects, however, specimens of which he exhibited to the meeting, were quite capable of being reproduced by the three-colour process. The success of that process depended a great deal upon the proofer; if the proofer would only have the original in front of him and ask himself what shades of colour were in that picture and then try to reproduce them accurately, a satisfactory result could be obtained, and one that would be much more economical to the process-engraver. With regard to the author's remark that "the conductors of the best illustrated newspapers had moderated their enthusiasm since the outbreak of war," that was a case of necessity. Their workmen had been taken away from them, sufficient quantities of paper could not be obtained, and also a great deal of the ink required formerly came from Germany, and was not obtainable at all at the present time. Such progress, however, had been made in the direction of producing the ink in this country, that he hoped after the war we should no longer have to depend upon Germany for ink. The

author mentioned that the recent issues of the principal illustrated weekly newspapers published in Germany showed no diminution in the amount of colour work they contained, and in that connection he had brought with him several copies of the *Illustrirte Zeitung*, which he exhibited to the meeting. He would like to point out that the German Government looked upon newspapers as very useful for propaganda work, and therefore gave them a good deal of assistance. Some of the most beautiful effects in colour printing had been produced by the aquatint method, which had really been superseded by three-colour work. The author's account of the "Renaissance" method was very interesting, and there was, no doubt, a very great future in front of it. He was glad to hear the author say that efforts were being made to find something better than the coated paper that was now so commonly used. An important committee appointed by the Society of Arts in 1897 had shown, by making inquiries and collecting evidence on the subject, that it was quite impossible to preserve coated paper for more than a few years. He remembered that one of the officials of the British Museum said that some of the expensive books in the Museum, printed on coated papers, had had to be cut to pieces and each page bound separately with a piece of tape.

Mr. R. A. Peddie said he had listened to the paper with great interest, especially that part of it dealing with the "Renaissance" machine. He had always had a great dislike for coated paper, and in certain papers he had written he had said some very unpleasant things about it. No doubt it had been a necessary evil, but he hoped that either the "Renaissance" process or some other process would come to the front and obviate the necessity for the use of coated paper. As the author had proved by the prints he had exhibited to the meeting, it was not absolutely necessary to use coated paper for three-colour or four-colour work, but presumably the whole question was one of cost. Books had been produced containing no coated paper at all, but they were very expensive—much too expensive for the general public to purchase. He was not speaking as a practical printer, but he thought the author would bear him out when he said that it was rather a question of spoilt sheets when non-coated paper was being used, because the surface was certainly not so fine as that of coated paper. He thought it was a little doubtful whether the non-coated paper would last much longer than coated paper, because he was under the impression that it had to be beaten very much more than ordinary paper, and—the length of the fibre being reduced very considerably—the tensile strength of the paper was consequently less. He had examined a great many aquatint reproductions, and had very rarely been able to find one printed entirely in colours; generally one or two colours, or at any rate one or two tints, had been added by hand.

Mr. Adam Black said that in certain instances coated paper had not begun to disintegrate after twenty-five years.

Mr. C. Abbott Pasquier said that the work reproduced by the *Graphic* prior to the introduction of the three-colour process was all done by the aquatint method, there being a great advantage in the depth of the plates and the long run made on the machines by that process, and very accurate facsimiles of the originals were obtained.

Mr. A. S. Jennings asked the author whether it was possible by either the three-colour or four-colour process to reproduce accurately the solar spectrum.

Sir Henry Trueman Wood, being asked by the Chairman if he could reply to Mr. Jennings' question, said he had seen a great many attempts to reproduce the solar spectrum, but had never seen anything which came near the original. He did not think it could be reproduced by the three-colour process. The only satisfactory reproduction of the spectrum he had ever seen was one by Professor Lippmann. It was very small and was not capable of being multiplied.

Mr. G. W. Jones, in reply, said that with reference to his remark that Germany was continuing to use colours for the embellishment of its weekly newspapers, he had recently been given to understand that the printing works that carried out the better-class work were not being used at present. He could quite believe that, because this country had been the happy hunting-ground of Germany in regard to colour printing, and naturally they would want to keep their plant as intact as possible, in order to regain their old markets as soon as possible after the war. With regard to rag paper, he quite appreciated its merits, and thought that the pictures in Mr. Barratt's book "Annals of Hampstead" looked very much finer on rag paper than they would have done on coated; but, on the other hand, coated paper often gave a clearer and sharper effect. He agreed with Mr. Peddie that the difficulty of printing on rag paper was that the surface of the paper was not so mathematically even. As he had pointed out in the paper, good colour work could not be obtained by "squeezing" it must be done by just sufficient "contact" of the paper and block. The cost of rag paper was very much greater than that of other paper. He was very sorry that, as he had stated in the paper, Messrs. Dickinson, owing to the difficulty of manufacture, had dismantled the special machinery they had erected at great cost for the manufacture of rag paper.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Jones for his interesting paper, and the meeting terminated.

ARTS AND CRAFTS.

The British Industries Fair.—This year, instead of dividing up so many of the exhibition halls at the Victoria and Albert Museum, the Board of Trade very wisely decided to house the toy section of the British Industries Fair in the Imperial Institute. The result of this plan was very satisfactory. Not only were lovers of the museum spared the shock which last year's erections inevitably gave them, but it must be admitted that the exhibition at the Victoria and Albert Museum gained in dignity and seriousness from the banishment of the toys, and from the fact that the buyer interested in, say, the printing trades or in pottery and glass did not have to make his way to his business through an avenue of teddy bears and other "soft toys." The new arrangement may have been due to difficulties of labour and construction, but it certainly made for the greater effectiveness of the exhibition as a whole. We in England have not the inborn faculty for arranging exhibitions, which is so marked a characteristic of our French Allies, but it is to be hoped that we are on our way towards acquiring some measure of competence in this respect. The toys last year were many of them excellent—there is, perhaps, no industry upon which the war has had so vitalizing an effect—but they were not the most fitting introduction to the exhibition.

Toys.—The soft toys this year did not make such an imposing show as they did in 1916, but the catalogue proves that they were exhibited by an even larger number of firms. Some of them had a real claim to artistic merit, but there is a tendency in certain quarters (especially, apparently, amongst the country and the semi-philanthropic makers) to produce a weird and rather unpleasing type of soft doll or animal which is rather striking in its effort after originality than genuinely attractive. Metal toys were naturally not peculiarly numerous, but there was an abundance of British-made soldiers, and their quality, artistically at least, showed a distinct advance, whilst in some cases their arrangement was not only ingenious, but gave evidence of real taste. The wooden toys, again, displayed a steady movement in the right direction, and many of the dolls'-houses, farms, shops, etc., displayed a real regard for artistic effect. This really seems the direction in which there has been most progress in the last three years. The building bricks planned to construct houses designed by a real live architect also showed a striving after beauty which was quite absent from the pattern sheets supplied with the building blocks of an earlier generation.

The Printing and Fancy Trades.—In the printing trades section there was, perhaps, nothing so arresting as one or two of last year's exhibits. The same firms show in the main, it is true, but they cannot issue striking novelties every year, especially in war time. The most interesting wares in this section were, perhaps, the children's books, many of which were charmingly designed and, though printed in the bright pure colours so dear to the heart of the child, they escaped any suspicion of crudeness in colouring. Messrs. George Harrap showed some very good children's books, and Messrs. Blackie and Son's exhibit, especially the set of drawings by Florence Harrison, was of very real interest. Messrs. A. M. Davis and Co. showed some admirable postcards, amongst which the flower cards of H. G. C. Marsh Lambert were deserving of special mention. They recall inevitably the work of Walter Crane and of Ottilia Adelborg—one can hardly imagine that they would have been produced had neither of these artists paved the way—but they are none the less charming. Messrs. Raphael Tuck's show included some rather amusing cards in bright colours with some affinities with cubism. The Medici Society's cards are in a class apart, and represent the highest point to which British makers have, so far, attained. Messrs. Dean and Son's stencil books, which contain plates ready cut, ought to be of considerable help in schools where it is recognised that, though there is no time to teach the children how to cut their own stencil plates, there is yet much which they can learn, in the way both of manual dexterity and of that arrangement which lies at the root of design, by stencilling units on a variety of plans. Fancy articles are not generally of any great artistic value, and the exhibits at the Fair formed no exception to the rule. It is interesting, however, to note that some firms are producing leather goods of the type with which German makers used in pre-war days to flood the Italian market with considerable success. Messrs. Henry Wolff and Co.'s lamp shades, especially those in orange silk decorated with really good patterns in black pigment of some kind which stopped out the light where it was applied and produced a most happy effect, were well worth notice. Mr. A. J. Rowley, whose "Artrec" work is now very well known, showed some experiments in lacquer on wood which promise well for the future.

Pottery and Glass.—The exhibits in the pottery and glass section were interesting on a rather different level from those of last year. Very few tiles were to be seen, and several of the firms best known for the production of artistic work of real technical excellence were unrepresented, whilst there was a larger amount than last year of more or less artistic work of the peasant type. Amongst this last the primitive-looking unglazed pottery shown by Messrs. Carter of Poole, which might have been imported from Mexico or dug up from some ancient tumulus, was by far the most attractive. It struck one as being rather brittle, but in its rude archaic way it was extra-

ordinarily satisfactory. There was a good show of Baron's Barnstaple ware, and the Ravenscourt Pottery sent some up-to-date work decorated fairly successfully with chequer patterns. Amongst work of more technical achievement the Upchurch salt glaze ware was distinguished by a certain dignity of form as well as by its rather cold and restrained colour. There was an interesting exhibit of Moorcroft ware which included some good lustre effects in blue and purple. The yellow lustre ware was not quite so successful in colour. Messrs. Shorter and Son showed some matt glazed vases with fine broken effects of colour, and there were some good examples, some of them rather overgilded, of Wedgwood china lustre ware. Messrs. Birks, Rawlins and Co. showed some *pâte sur pâte*, which, though not by any means so delicate as M. Solon's work used to be, was a good deal better than the average. The glass trade was well represented. Messrs. Webb of Stourbridge sent an interesting collection of glass, and the stand of Messrs. Stevens and Williams of Brierly Hill included, amongst other work, some very successful rose bowls. Mr. and Mrs. Reginald Hallward's stall showed how much can be done to enhance the attractions of the exhibits by a tasteful arrangement of the space at the exhibitor's disposal.

GENERAL NOTES.

HENNA.—Henna, which has been used from the most remote times as a dye plant, is the subject of a monograph by F. Cortesi and G. Tommasi published in *Annali della R. Stazione Chimico-Agraria Sperimentale di Roma.* The Arabs employ it as a cosmetic for different purposes, and also as a medicinal plant. Its dyeing qualities are widely utilised for wool, silk, and wood. The plant is extensively cultivated in the fields of Tripoli, always under irrigation. The plantlets are raised in nurseries, and transplanted in the spring, in parallel rows at a distance of 50 by 50 centimetres. No manure is applied, but irrigation is carried out every six days. The plants are cropped for about twelve years, the maximum growth being reached in the second or third year. The crop is usually taken off in February, and again in August or September, the whole of the above-ground portion of the plant being cut. The annual yield of dried leaves varies from 15 to 19 cwt. per acre.

THE PAPER INDUSTRY IN THE U.S.A.—The latest census of manufacturers in the United States shows that in America the manufacture of paper is second in importance only to the steel industry. The total invested capital is estimated at $500,000,000, while the annual value of the manufactured product of the paper and pulp amounts to $350,000,000.

CHINA COTTON-SPINNING AND WEAVING INDUSTRY.—According to a report by the Canadian Trade Commissioner at Shanghai, the development of the cotton-spinning and weaving industry in China is worthy of careful study. Scarcely more than thirty years ago not a single cotton-spinning or weaving mill fitted with an up-to-date plant and operating on modern lines could be found in China. By careful inquiries it has been ascertained that thirty-seven such mills have been established since then. Now that a start has been made, a more rapid and extensive development in this branch of industry in the future may confidently be expected. Of the thirty-seven cotton mills, twenty-one are situated in Shanghai, while the rest are scattered throughout the four provinces of Kiangsu, Chekiang, Hupeh, and Honan. Most of the larger and more flourishing mills at Shanghai have been established and are working under foreign direction. There are five Japanese seven British, and nine Chinese mills in Shanghai, the latter including two in the course of being established. One of the British mills, having 72,264 spindles and 580 weaving machines, is the largest, and the Nisshin mill (Japanese), operating 10,000 spindles, is the smallest. The total number of spindles in the twenty-one mills at Shanghai is estimated to be 642,984, and the number of weaving machines to be 3,204, including those of the two Chinese mills not yet working.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

APRIL 18. — HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance."

APRIL 25.—SIR FRANCIS FOX, M.Inst.C.E., "Flour and Bread." CAPTAIN CHARLES BATHURST, M.P., Parliamentary Secretary, Ministry of Food, will preside.

MAY 2.—J. C. SHENSTONE, F.L.S., M.P.S., "Herb-growing in the British Empire: its Past, Present, and Future."

MAY 9.—PROFESSOR WILLIAM RIPPER, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

MAY 16.—SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

INDIAN SECTION.

At 5 p.m. :—

TUESDAY, MARCH 27. — SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., M.D., F.R.C.S.,

President, Scientific Advisory Board, Indian Research Fund Association, "Opportunities for Original Research in Medicine in India." The RIGHT HON. AUSTEN CHAMBERLAIN, M.P., Secretary of State for India, will preside.

At 4.30 p.m. :—

THURSDAY, APRIL 19.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

Date to be announced later :—

D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

HOWARD LECTURES.

Monday afternoons, at 4 p.m. :—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies." Two Lectures. (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market. April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 26...Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. J. Falconer, "The Ploughing up of Grass Land and its Subsequent Treatment."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Miss M. Ashworth, "The Education of Women in India."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m. Professor H. S. Foxwell, "Inflation: In what sense it exists; how far it can be controlled."

TUESDAY, MARCH 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. (Indian Section.) Sir Havelock Charles will read a paper by Surgeon-General Sir C. Pardey Lukis, "Opportunities for Original Research in Medicine in India."

Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Professor L. W. Lyde, "Europe *v.* Middle Europe."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. W. Gregory, "Geological War Problems." (Lecture III.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. H. Allcock, "The Decimal System of Coinage, Weights and Measures."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. R. P. Howgrave-Graham, "Chaucer's Pilgrim's Way—From the Tabard Inn to Canterbury *via* Sittingbourne."

Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Miss M. E. Durham, "South Slav Customs and Beliefs as illustrated in Old Ballads and in Tales by Serb Authors."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m. Mr. J. Baker, "The Kingdom of Bohemia: a Buffer State against Berlin."

WEDNESDAY, MARCH 28...Naval Architects, Institution of, at the ROYAL SOCIETY OF ARTS John-street, Adelphi, W.C., 11 a.m. (Annual Congress.) 1. Chairman's Address. 2. Mr. D. B. Morison, "Standardisation as Applied to the Machinery for Cargo Boats." 3. Mr. W. J. Lovett, "On a Method of Obtaining for Ship Design the Spacing of Bulkheads according to the Rules of the International Convention."

3 p.m. 1. Mr. J. Montgomerie, "Stress Determination in a Flat Plate." 2. Signor E. Benvenuti, "The Closing of all Ship Side Apertures from the Bridge." 3. Mr. T. Graham, "Description of an Apparatus for Interpreting Stability for the use of Shipmasters."

7.30 p.m. 1. Professor W. E. Dalby, "The Strength and Inner Structure of Mild Steel." 2. Lieutenant W. A. Scoble, "Design of Pin Joints based on Ultimate Strength."

Japan Society, 20, Hanover-square, W., 5 p.m. Dr. Haga, "The Spirit of Japan (Yamato Damashii)."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Right Rev. Bishop Boyd-Carpenter, "Dante and Boethius."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Lieut.-Colonel Sir Alfred P. Gould, "Personal Habits in relation to Public Health in Time of War."

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Mr. F. Dixey, "The Carboniferous Limestone on the South-Eastern Margin of the South Wales Coalfield."

THURSDAY, MARCH 29...Naval Architects, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 11 a.m. 1. Mr. W. J. Luke, "Further Experiments upon Wake and Thrust Deduction Problems." 2. Mr. J. J. King-Salter, "Some Experiments on the Influence of Running Balance of Propellers on the Vibration of Ships." 3. Sir George Greenhill, "Theory of Wave Motion on Water."

3 p.m. 1. Mr. J. H. Macalpine, "Marine Application of Reduction Gears of Floating Frame Type." 2. Messrs. P. A. Hillhouse and W. H. Riddlesworth, "On Launching." 3. Professor W. Hovgaard, "Buoyancy and Stability of Submarines."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Mr. W. Bateson, "Professor T. H. Morgan's Work on the Mechanism of Heredity."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Miss E. F. Smythe and Principal S. Hicks, "Vocational Guidance and the Trade School."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. A. Fleming, "Modern Improvements in Telegraphy and Telephony." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. A. A. Campbell Swinton, "Forty Years of Progress."

China Society, Caxton Hall, Westminster, S.W., 3.30 p.m. Dr. L. Giles, "Ch'iu Chin: a Chinese Heroine."

FRIDAY, MARCH 30...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor J. H. Jeans, "Recent Developments of Molecular Physics."

SATURDAY, MARCH 31...Royal Institution, Albemarle-street, W., 3 p.m. Mr. S. Graham, "Russian Idealism: the Ideas of the Russian Philosopher, Vladimir Solovyof." (Lecture II.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 23, 1917.

Journal of the Royal Society of Arts.

No. 3,358. VOL. LXV.

FRIDAY, MARCH 30, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

DEATH OF H.R.H. THE DUCHESS OF CONNAUGHT.

At their meeting on the 26th inst. the Council passed the following resolution :—

"The Council of the Royal Society of Arts desire to offer to the President of the Society, His Royal Highness the Duke of Connaught, their humble condolence on the occasion of the death of His beloved and popular Consort, and to tender to His Royal Highness an expression of their dutiful and loyal sympathy with Him in His bereavement."

INDIAN SECTION.

Tuesday afternoon, March 27th, 5 p.m.; THE RIGHT HON. AUSTEN CHAMBERLAIN, M.P., Secretary of State for India, in the chair. A paper on "Opportunities for Original Research in Medicine in India," by SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., M.D., F.R.C.S., President, Scientific Advisory Board, Indian Research Fund Association, was read by Surgeon-General Sir R. Havelock Charles, G.C.V.O., M.D., F.R.C.S.I., President, Medical Board, India Office.

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, February 27th, 1917; Mr. W. A. S. HEWINS, M.P., in the chair.

The paper read was—

THE EMPIRE'S ASSETS AND HOW TO USE THEM.

By ALFRED BIGLAND, M.P.

Before entering upon the detailed consideration of my subject I should like to place before you, by way of preparation, one or two brief illustrations designed to indicate certain axiomatic truths which serve as a starting ground for my subsequent remarks.

A near relative of mine, who is an artist, painted a very large picture which many of us so admired that we begged him to have it reproduced in colours on a small scale. Accordingly, he commissioned a competent firm to do the work, and the reproductions were faithfully made; but, to everybody's great disappointment, there was something wrong, yet it was difficult to tell what. The details were reproduced accurately, and the colourings were the same; yet the effect was quite different. The trouble was simply this, that the reproduction was too faithful. The same colours, which in the original blended harmoniously, in the reproduction were crude. In other words, the process of reproduction failed to take account of the different scale.

To take another illustration. A poor city clerk is suddenly faced with some liability far in excess of his annual income. What does he do? Having no capital he has to raise the necessary money and repay it, maybe, at high interest, to some usurer over many years; in fact, his whole life may be blighted by the burden thrown upon him. But a company confronted with a similar liability acts very differently. It may have to realise certain assets, but more probably increases its capital and launches out in fresh activities, in order to make up in one direction for what has been lost in another. A huge combine thinks nothing of a financial blow that would stagger a firm organised on ordinary lines, but sets to work to extend its operations—probably emerging ultimately from the struggle with an adverse situation even stronger than before, with its interests more widespread and its prosperity on a broader foundation. The larger the body the more easily can it overcome financial difficulties, even though these difficulties may be greater in proportion than those sufficient to afflict and overwhelm smaller concerns. But the point to be remembered is that the large body succeeds by reason of its larger resources, which enable it to employ methods inapplicable to the small concerns.

I wish to put before you to-day the position in which this Empire and its Allies will find themselves at the conclusion of the present war, and to make some suggestions for a combined economic policy designed on the one hand to meet the huge liabilities consequent upon the war, and, on the other, to increase the prosperity, comfort and security of the nations and peoples concerned; while, at the same time, affording a means of restraining the harmful activities of the present enemy powers, and of administering to their peoples such a measure of retribution as the Allied Governments may think fit.

From my prefatory remarks you will, I hope, have gathered that, in my view, the after-war problems must be approached with a mind prepared always to remember the scale of the matters involved; to remember that we are dealing, not with individuals, firms, combines, or even separate nations, but with the most powerful league of nations ever known. Consequently, the petty objections, prejudices, and obstacles appropriate to the consideration of the affairs of small bodies are entirely out of place when applied to the economic problems of so vast and powerful a comity as the Entente Powers.

After the war there are many problems to be faced, but of these the most important are the payment of the war debt, the feeding of the people, the provision of work for our ex-soldiers, and the rehabilitation of the devastated areas. What means are we going to adopt? Are we going to saddle our taxpayers with this grievous burden, as the clerk, of whom I have spoken, is saddled with the money-lender's interest? Surely we should avoid this at all costs—and the way is easy.

Within the Allied Empires are tremendous resources, capable of development by means of relatively small capital expenditure into assets of immense value, which could be realised in such a way that the entire war debt could be liquidated, even allowing for post-war borrowings on behalf of devastated France, Belgium, Poland, Serbia, Rumania, and Montenegro. The development of these resources would provide employment for our demobilised armies, either in the field or in the workshop; would render possible the provision of foodstuffs in the huge quantities that will be required by the Allied peoples; would set up homes in parts of the Empire now unpeopled, and would provide a splendid reserve of trained seamen for the Allied nations.

The principle of State development in our Empire for the benefit of State and people has already been advocated in the public press and elsewhere, notably by Mr. Wilson Fox, M.P., of the British South Africa Company, in articles published in the *Times* newspaper of September 28th and 29th, 1916, and in a paper read to this Society on December 13th, 1916. An influential committee—the Imperial Resources Development Committee—has resulted, to which I have the honour to belong, and a very favourable reception was accorded by public opinion to this Committee's manifesto published in the press on February 5th last.

Briefly put, the objects of the Imperial Resources Development Committee are to foster the project of further developing on business lines under State auspices—by means of an Empire Board, working aloof from politics or party—such Empire resources as may prove suitable and obtainable. The resulting profits, whether by way of direct sales of produce or royalties on production, or by way of increased capital value realised on sale, should amply suffice within a reasonable time to pay off the entire war debt without taxation, yet leaving the Empire more prosperous than before. The incidental benefits of such a scheme, to the Empire as a whole and to the producing areas developed, will best appear from a study of the examples which have thus far been considered in greater or less detail by the Imperial Resources Development Committee.

Before embarking upon the consideration of such examples, however, it may be well to revert once more to the essential importance of adopting new methods of finance in the face of a post-war liability of such unprecedented magnitude. Assuming our own war debt to be four thousand million pounds—almost certainly an *under* estimate—that sum works out at about £500 per family. To pay off this £500 would require about 15*s.* per week in interest and sinking fund. How many poor and middle-class families could afford this? Remember, too, that it is easy for the wealthier classes to "pass on" any increased taxation by the process called "cutting down expenses"—a euphemistic term for diminishing other people's earnings by doing without certain services which the other people render.

What hope would there be of money being voted by Parliament and the rating authorities for social reform, in face of such a terrible hole in the national pocket? We know, for instance, that school teachers are underpaid, as compared with members of other professions for which

equivalent training and study are necessary. Workmen's houses, old-age pensions, afforestation, and cheaper telephones, are other instances where the essential money would not be forthcoming. Almost certainly the Poor rate would rise—but with that we should like to dispense altogether.

Under such burdensome conditions, life in Britain would be unbearable for the best of her sons, who would chafe until they broke away, emigrating to some more favoured country. That would only make matters worse.

With these considerations in mind, and remembering the scale of the matters involved, it is clear that new methods *must* be adopted. We turn again, then, to the idea of Empire development, prepared to search the future with prophetic glance and discern, so far as may be, the results of the practical working of a scheme of the nature indicated.

Accepting, then, the principle of State development of Empire resources for the benefit alike of State and peoples, let us next consider certain specific examples of appropriate resources. We shall then be in a position to consider how present Allies, Neutrals and enemies would be affected, and to indicate the lines of a common economic policy.

My present remarks are not, however, to be taken as an official exposition of the views of the Imperial Resources Development Committee, but as conveying my own personal views, more especially as regards certain extensions and economic consequences of the policy advocated by that Committee.

I will first touch briefly upon Mr. Moreton Frewen's suggestion of an Empire Farm, dealt with by him in a paper read recently to the North-East Coast Institution of Engineers and Shipbuilders. The development of millions of acres of new wheat lands, favourably situated as to climate and relatively accessible from Hudson Bay, would in itself be a magnificent achievement. But note the results: by creating enhanced value in such land by preliminary development and preferential treatment, and then disposing of the land, on the gradual payment system or otherwise, we should in the first place be repaying part of our war debt—but there is more than this. Canada would benefit by the added population and commerce, the Empire would be made more nearly self-supporting in respect of wheat, and the manufactures of the home country would find a new market.

It is only just, however, to emphasise that the practical success of the Empire Farm proposal is dependent, in my opinion, upon the imposition in the United Kingdom of an import duty on wheat from countries outside our Empire and our Allies. Such a duty would bring about an immediate increase in the cash value of this fertile soil within the Empire. Land in the Empire to-day only worth a dollar an acre would become worth £20 an acre when provided with subsidised cheap transit, railways, and guarantees that all it produces will find a better market than similar articles produced under any other flag. These advantages will draw the necessary workers; and the Dominion which assists and facilitates this transfer of its land to the Empire Development Board will reap the harvest all new countries covet—a settled well-to-do body of citizens, constituting man power and a widening taxable area.

I would wish to invite your especial attention, however, to other examples regarding which my forty years' business experience has given me an intimate knowledge. The first of these is provided by the British Possessions in West Africa. In addition to mineral wealth in the shape of tin and copper, these Colonies contain valuable areas of timber and are capable of producing cotton and rubber; but these are not the products on which I would particularly lay stress. West Africa is, however, the home *par excellence* of the oil palm, from which the natives obtain two products of tremendous importance. The fruit of this palm comprises an outer pulpy mass which, when boiled in water, yields palm oil; within this mass is a cluster of nuts not unlike small Brazil nuts, and these when cracked yield kernels containing nearly 50 per cent. of the richest vegetable oil known.

The crushing of the kernels to obtain the oil was, before the war, almost entirely a German industry; but steps have now been taken to establish the industry in this country and to eliminate the German interest in West Africa.

All my hearers will be familiar with the recent discussion in Parliament respecting what was called the "Nigerian Sale," the question then being whether certain properties established by Germans should be sold only to Britons and their Allies, or thrown open to Neutrals. The latter course was maintained, contrary to my own views; but it is satisfactory to be able to state that the properties of value were in fact acquired by British firms.

To return to the fruit of the palm: we see, then, that this yields oil called "palm oil," and kernels called "palm kernels," the latter providing when crushed another oil—"palm kernel

oil"—and a residual cake—"palm kernel cake."

All these three products are of the greatest value; the oils are the stock raw material of the soap and candle makers, and in this connection during the war have assumed enhanced importance because the soap and candle makers in their manufactures extract from the oil glycerine, serving as the basis of our cordite.

Palm kernel oil, in addition, is a large ingredient of margarine, and most certainly the consumption of margarine is unlikely to diminish—in fact I hesitate to assign to it any limit. The cake, when blended with molasses and other materials, forms an admirable food for cows and pigs, as the Germans long since discovered.

In the oil palm alone, then, West Africa possesses a most valuable asset, but this by no means exhausts her vegetable wealth; from the Gambia, for instance, come the finest ground-nuts known, large quantities also being produced in Nigeria and the other Colonies. These ground-nuts are also called earth-nuts, pea-nuts and monkey-nuts. From them a most valuable oil can also be pressed, and a cake useful for fodder obtained; but to these I do not attach so much importance as to the palm produce, because of this latter British West Africa possesses a virtual monopoly.

As proof of the value of this monopoly, I cannot adduce better evidence than what is happening at the present time. On account of the importance of palm oil as a source of glycerine, we allow the exportation of it to our Allies, but not to Neutral countries; nevertheless the Neutrals are so badly in want of this oil that their merchants have come to terms with us, and agree to give us the glycerine content of the oil as a condition of being permitted to import it.

When I tell you that the entire supply of glycerine in this country is requisitioned at just under £60 per ton, and the corresponding price in America, for example, is nearer £200 than £150, you will appreciate that the Neutrals consider our oil to be of great value and worth paying a good deal to obtain.

There is, in addition, a small export duty on palm kernels and oil which has been imposed for Colonial revenue purposes, but this applies to exports to all destinations, and does not affect the present arguments.

The only other product of West Africa which need be mentioned here is cocoa, of which enormous and increasing quantities are being obtained year by year. The popularity of cocoa products, such as chocolate, shows no signs of diminution, and we may reasonably anticipate that cocoa will not in the future form a less valuable asset than at present.

Think what it would mean if all these products of West Africa, mineral and vegetable, were controlled for the benefit of the Empire as a whole! Think how huge is the potential profit which could be devoted to the service of the Empire's debt.

One criticism I would here reply to in advance, and that is, the objection that the profit resulting from the development of West African produce under State auspices would be an unfair profit derived from the people, upon whom it ought to be spent by a reduction in the price of the manufactured articles concerned.

In the first place, I would point out that the present prices of the manufactured articles are eminently reasonable. No one, for instance, can cavil at 9*d*. per lb. for margarine, which is the price that has been maintained even in war time. Consequently, the continuance of about the present prices, which forms one element of the proposal, would be quite unexceptionable. Furthermore, were the matter left in private hands, no reduction in price, even of the raw materials, would be at all probable; for apart from commercial reasons which would lead the parties concerned to maintain present prices, there is the fact that no such cheapening of the supply could be brought about by private endeavour as could be effected by State enterprise operating on an almost infinitely larger scale than would be possible to private traders, or even large companies.

There is yet another consideration, namely, that the manufactured article is disposed of to the consumer in such small quantities in the retail trade that a very large margin of profit on the raw materials taken in bulk represents the most trifling proportion of the retail price. Let anyone who doubts this work out what a halfpenny per pound in the price of margarine would represent on the cost of the raw materials manufactured into the margarine consumed in the United Kingdom. At present this consumption of margarine is, approximately, 3,500 tons per week, and a halfpenny per lb. works out at about £16,000 on the raw materials. This is *per week*, and equals a trifle of £800,000 per annum. This is for one manufactured article only, margarine, and is apart from the other manufactures employing West African oils.

The direct profit from the West African produce by no means exhausts the benefits which would result from the possession and the

development by the State of the trade in such produce. In addition to providing most important supplies of food and raw materials for our British industries, the adoption of the scheme proposed would, it is clear, benefit the Colonies concerned most materially.

In British West Africa are about 17,000,000 natives and only 6,000 whites. The proposed development scheme would afford a splendid means of facilitating the civilisation of the natives, as their labour would be harnessed to the chariot of progress and productiveness, and their purchases would to a greater extent than at present be under Government control, thus in time enabling the disastrous gin traffic to be done away with entirely. Means of communication would be improved; schools and model villages built, and, in short, British West Africa would be advanced immeasurably.

The prosperity of the Colonies, moreover, is synonymous with that of our Lancashire factories, and others, which supply the natives with their manufactured goods; in proof of this it will suffice to state that the African merchant, who at present purchases palm produce, reckons to make the major part of his profit, not out of this produce, but from Manchester goods which he sells or barters to the native.

To one point I wish to draw your particular attention, and it is that the West African resources are not undeveloped, although capable of much further development. The oil palm, for instance, now growing wild might well be susceptible of improvement by the application of scientific methods. It is no part of the general scheme here outlined to spend State capital upon wild-cat schemes as yet untried. Every proposal put forward would have most carefully to be scrutinised; but here is a proved success now yielding a handsome profit, and capable of great enhancement. Within the Empire are many other such waiting, almost crying, to be taken over.

Space prohibits my going into detail with regard to other instances; but I may perhaps mention the untold wealth in the supplies of fish within the Empire's territorial waters, of forests hitherto untouched, minerals yet unmined, and crops yet unsown.

Every article and every industry, and every Colony and Dominion concerned, would require special consideration, and the apportionment of the share of the State in the profits. For example, in dealing with minerals as yet undeveloped or perhaps even undiscovered, a policy would be necessary differing largely from that appropriate to vegetable produce. Also, portions of the Empire suited to be the home of white people would require to be developed on altogether different lines from tropical lands, where home life, as we understand it, and the nurture of white children are impossible.

Enough has been said, surely, to convince everyone that the liabilities consequent upon the war can be faced with equanimity if we and our sister States grapple resolutely with the situation and bring to bear the tremendous resources of the Empire.

I would like to add a few words, however, as to fish, and to point out that, although tremendous quantities are already landed and consumed in the United Kingdom, amounting to about 600,000 tons in 1913, these quantities might be greatly increased by extension of supplies, and improved methods of distribution and storage. In my opinion there is almost certain to be a continuance of the high price of meat, especially beef, and a remedy is to substitute a larger proportion of fish than at present in the dietary of our peoples. The seas around our Empire teem with splendid fish. As a Canadian Bluebook well puts it: "To say that Canada possesses the most extensive fisheries in the world is no exaggeration; moreover, it is safe to add that the waters in and around Canada contain the principal commercial food fishes in greater abundance than the waters of any other part of the world." Yet in 1915, according to the same publication, there were only 48 steam fishing vessels; 1,236 sailing and gasoline vessels; 25,105 sail and row boats; 7,740 gasoline boats and 431 carrying smacks engaged in the Canadian Fisheries. These do not include the figures for Newfoundland, in whose cod fisheries 2,000 schooners and 25,000 boats are engaged.

Not the least important aspect of the fisheries question is the large consumption in other countries of cod, herring and other fish, pickled and otherwise; for instance, apart from Germany and North European countries, large amounts are taken by Greece, Italy, Spain, Portugal, and Brazil. Under State auspices, and with a comprehensive system of supply and distribution, a huge world trade could be built up, and care would, of course, be taken to ensure that our Allies received the greatest possible advantage resulting from the increased supplies.

I must not omit to mention the whaling industry, carried on mainly in the waters of the Antarctic Ocean by companies largely

foreign, under licences granted by the British Government. Last year these regions produced 100,000 tons of whale oil, worth £3,000,000, the whole of which was bought by the Ministry of Munitions for use in making glycerine for explosives, and for other purposes vital to the war. This purchase affords sufficient evidence, without further comment, of the value of this Empire asset.

One general feature of State-aided operations such as we are considering, is that special attention would be paid to the welfare of the individual worker. The Empire could well afford to treat handsomely the existing interests and to enlist their co-operation as agents in further development.

This scheme might truly be called a State partnership, where the native producer, the merchant, and the steamship owner would all be secured shareholders, certain of their remuneration, and the State would take no share unless and until the value of the produce in the markets of the world enabled it to obtain a profit in excess of all legitimate cost of production and transit by private enterprise. This as a principle of State policy was unknown in practice until the war, but we are all familiar with the fact that the State, by means of the Munitions of War Acts and the Excess Profits Tax, has made itself partner in every successful business in the kingdom. In the case of all munition firms, after pre-war profits have been made and 20 per cent. added, the rest is the State's share in the partnership. The proposal I am laying before you is that this system should be applied on a broader basis, and that other industries should be made partners with the State in the development of State resources.

Every encouragement possible ought to be afforded to individual effort, and the workers should participate in the benefits without the least taint of exploitation.

But some may say that with a scheme of such unprecedented magnitude there is nothing to guide us in the matter of procedure, engagement of staff and the like. Fears may even be entertained that vital commercial questions would be left in the hands of a college-trained bureaucracy and thereby foredoomed to failure. To this I would reply that we have the experience of the great combines to help us, and can profit by their successes while avoiding whatever may be unfair about their business methods. What is probably the greatest combine in the world—the Standard Oil Company—deals with its staff in a manner, to my mind, wholly admirable. Each person holding a responsible position is specially selected, and is then given an absolutely free hand within certain prescribed limits. The credit of the Company is at his disposal up to a specified amount, to be used in whatever directions he may think fit. This affords to a man of initiative and ability opportunities such as in no other circumstances in ordinary commercial life could be his, for the credit of the combine is so immense.

No doubt occasional blunders are made, and those who fail to fulfil the trust placed in them are superseded; but the point I wish to emphasise is that they are given a chance to show what is in them, and are not penalised for making occasional mistakes. The great and haunting dread at the back of the mind of the ordinary official, as I understand it, is fear of committing his department. Can it be wondered at that lack of initiative is frequently urged against officials burdened with such a dread? Timidity is a logical outcome of lack of responsibility, and that is what the suggested Empire Development Board would carefully avoid.

How are these proposals likely to be received by that very important department of the community—organised labour? I would answer this by drawing attention to the recent conference of the Labour Party, which emphatically protested against the imposition of heavy taxes to meet the liabilities of the war, but recommended instead conscription of wealth. Here is a way in which the State can conscript wealth without hurting anyone—that is, the State can conscript the State's *own* wealth and make itself wealthier still.

Taking it as proved then that development of Imperial assets on the lines suggested is desirable in principle and feasible in practice, let us turn our attention to some allied and consequential economic questions.

It is clear in the first place that the foregoing proposals would form but a part of that closer Empire union which all anticipate will succeed the war.

The component portions of the Empire which have sent their sons to battle side by side and to work in the same factories, and which have taken upon themselves burdens for the commonweal, are bound to treat one another in the future on more favourable terms than they give to the present Neutral States. There seems an almost general consensus of opinion that Imperial Preference is a necessary consequence of the present war, and, as announced in the *Times* of

February 14th, Lord Balfour of Burleigh's Committee on the Paris Resolutions has presented an interim report unanimously in favour of establishing Imperial Preference. Such a preference would naturally be so arranged as to assist Empire development.

On grounds of sentiment and security alike there seems no other course in order to render the Empire self-supporting, and to draw closer in peace by economic methods the bonds of unity which have proved so valuable and so magnificent in war.

The extent of the preference is a matter for consideration by delegates from the Empire, but we shall not go far wrong in assuming for the sake of argument the Canadian figure of 33⅓ per cent. rebate in all Customs duties in favour of goods produced within the Empire.

This in itself is not enough to ensure, not merely the maintenance but the extension of supplies from the Empire of what may be termed vital articles, whether in the nature of food or raw material. The end to be attained is that the Empire should be self-supporting in all essentials. Already these essentials are provided in large proportion, as, for instance, wheat from India, Canada and Australia, but it is necessary to ensure that the proportion shall be sufficient to enable the Empire to "carry on" in time of stress without external supplies.

The most workable method for bringing about this consummation is, in my opinion, to impose a heavy import duty on supplies coming from *outside* the Empire as soon as the supplies derived from *within* the Empire reach half of the amount which has to be imported. It is of no use shutting out foreign supplies until we know that in large part we can rely upon our own. On the other hand, when that point has been reached, we can, by placing our Imperial producers in a favourable position, enable and induce them to expand their activities to such an extent that not merely will they within a comparatively short period of years entirely supply our British requirements in the articles concerned, but produce a surplus exportable elsewhere.

In cases where the Empire producers did not supply 50 per cent. of the imported requirements of this country, but did produce, say, 40 per cent. of this amount, it is clear that they would spare no effort to bring their production up to the necessary figure, knowing the prize that would be theirs on attaining that figure.

It would be worth while to sink capital in the production of an article in the Empire with the knowledge that by increasing that production by 25 per cent. the industry would be placed in a much more favourable position than at present. By this means, therefore, we should, within, say, ten years, place our Empire in a position to rely absolutely upon itself, and within a few years more to enter other markets in a very strong position.

It should, however, be made clear that other measures would be necessary in the case of articles of which it is desirable to foster the production within the Empire, but which at present are not grown to anything like 50 per cent. of our requirements.

Hitherto we have spoken more particularly of our own Empire, but the schemes here outlined, both of development and of preference, could readily be adopted by our Allies. The mineral wealth of Russia is fabulous, as also the value of her forests, fields and flocks. These resources afford a splendid field for British energy and capital, and concessions in this direction might well be obtainable, as also a preference in the carrying trade with Russia, in exchange for the products and manufactures which could be offered as a result of a scheme of Empire development under Imperial Preference. Imperial Preference would thus grow into Allied Preference, assisted by a scheme of Empire development.

France, in return for the supplies of foodstuffs and other raw materials which our development scheme would put us in a position to supply, might grant us tariff concessions in her own home markets—and the wonderful purchasing power of the French is sufficiently well known for the value of such a concession to be realised by all.

Belgium's home requirements will also be very great for a long time, and State-controlled resources in the British Empire would provide an admirable source whence these could be supplied. Moreover, in Africa, France and Belgium together possess territory of much greater area than the whole of British West Africa, having railways and systems of irrigation made and projected. These Colonies comprise resources capable of development on lines similar to those of our own, and combined or allied schemes would merit most careful consideration by the Board of Development which the Imperial Resources Development Committee desire to have constituted.

Let it not be thought, however, that I suggest driving hard bargains with our splendid Allies; the concessions I have touched upon would be granted freely by them or not at all, after we

had given first. Both as to the fish, West African, Indian and Colonial products, which would result from the development scheme indicated, and as to the preference, I would admit our Allies with our Empire, in the certain hope that they would, in their turn, grant us concessions in their markets and in their territories as freely as we gave them in ours.

Let us now try to contemplate the outcome that might well result of a league of Allied States, self-reliant, self-supporting, self-sufficing; freed from the burden of the war debt by schemes of development which would keep their population employed, their factories busy, their steamships filled and their citizens prosperous. The existence of such a comity, by reason of its strength, not merely in a naval or military sense, but economically and commercially, would go far to render war impossible.

Such a union would be enabled to impose its will upon the world, but its very diversity of peoples would afford sufficient guarantee against any narrow-minded action on its part. The present enemy Powers, deprived of colonies and allowed to trade only on sufferance, could never regain their former position in the countries of the Allies. Peaceful penetration on their part could be stopped as effectually as the road to Calais was barred, and, if necessary, a licensing system could be continued as regards trade in materials of vital importance. This last point, however, goes rather beyond the scope of my subject, and I will abstain from pursuing it further on the present occasion.

It remains to deal with one or two criticisms not already considered. Mention has already been made of the possible objection that individuality and initiative will be killed by the institution of monopoly, and I need only add that, so far from initiative being diminished, it would be increased by the friendly rivalry between different branches of the organisation to produce the best results. Considerable rewards would await the most successful—not necessarily those branches which actually brought in the most hard cash, but those who had made the most in the best sense of the resources entrusted to their care.

A further objection is that the policy outlined reeks of "Socialism." This much-abused word covers a multitude of policies—in fact, as many as there are Socialists; but, surely, we are all Socialists at heart, in so far as we strive for the good of the entire social organisation. In my view, the policy advocated affords the best antidote to the vicious doctrines commonly described as Socialism, which have as their basis the plundering of the successful for the benefit of the glib.

Yet another objection is that the proposed policy violates the principles of Free Trade. To this I would reply that the logical outcome of the policy is a gigantic scheme of Inter-Allied Preference, under which the trades that matter would be freer than they have ever been before, in that they would have liberty combined with safety in a wider sphere.

If any should urge that it is wrong for the State to undertake risks, and that undue risks attach to the schemes proposed, the answer is that it was wrong to spend money on the Assuan Dam, on the Indian State Railways, on a Government Postal Service, or if you will, on the British Navy.

One other possible misapprehension remains to be dealt with, namely, that to institute a scheme of Empire development it is *necessary* to lump together the entire war debts of the several Dominions with those of the Mother Country. Such a course might be adopted, it is true, after mature consideration, but this is in no sense an essential feature of the scheme, and for that matter such a scheme could be undertaken on behalf of any one or more of the several debts contracted. What is wanted is the institution of a Development Board, charged in the first instance with the repayment of the debt contracted by Great Britain. The Dominions would, in all probability, gladly join in, and arrangements to that end would be easy to make. To such a Board would be handed whatever resources might be offered by the several Governments of the Empire, or by private persons or companies.

The relations of this Board to the several Governments of the Empire would be such that, while holding itself quite aloof from all politics and secure from political interference of any kind, the Board would be able to bring before the various Parliaments of the Empire such legislation as might be required to carry out its schemes.

In conclusion, I would urge with all the force at my command the imperative necessity of this question of the repayment of the war debt being considered with the most open of minds by the great War Council, which is shortly to meet in London.

If, as a result of their deliberations, the several Dominion representatives return to their homes with the news that a Board of Development is to be set up to consider proposals, and to prepare for action on the lines I have indicated, the next

step will be that the several Dominions and Colonies will gladly come forward with the cry "Here are our resources; we give them as we have given our sons and our treasure for the service of King and Empire; take them and use them."

DISCUSSION.

The Chairman (Mr. W. A. S. Hewins, M.P.), in opening the discussion, said nobody knew what the financial burden on the Empire would be as a result of the war, but as far as could be seen at present it would overtop £4,000,000,000. Most people who had studied the subject would agree that our war finance marked a new departure in the financial history of the country more momentous than it had ever been before. The country would never go back to the old level of expenditure. It would pay off its debts and reduce the demands upon its purse in one way or another, but the war would be found to have lifted the level of expenditure. He thought a good deal of our finance had been managed on the assumption that there was some mysterious capital draft upon which it was possible to draw indefinitely without paying any regard to productive energies. There could not be a greater fallacy, and there was no way in which our obligations after the war could be met except by developing the resources of the Empire. About eighteen years ago he gave three lectures in the Hall of the Society on Imperial Policy. Those lectures arose out of the situation in Germany, where they were revising their general tariff, just at the beginning of the development of the German policy which had resulted in the present war. He then hazarded the opinion that it might make for peace as well as for the productivity of the Empire if our resources were organised, and, looking back over the eighteen years that had elapsed since, he did not think there was anything material left of the system that was in being at that time. The philosophies that underlay the policy upon which our Imperial concerns were conducted had been proved on many a battlefield to have been quite as false as anything that could be entertained. He also remembered giving a course of many lectures in the Hall of the Society extending over several years on the historic Acts of Parliament under which the wages of labour were regulated, and he then hazarded the suggestion that force of circumstances would bring English people back to their historic traditions. He did not then think that Mr. Lloyd George would announce in the House of Commons, as he did on the previous Friday, that they had returned to them. The lines of policy which the author had sketched out for the organisation of the Empire had been a subject of the greatest controversy, but he had never been able to understand why. The author had mentioned that the Committee on Commercial and Industrial Policy, under the chairmanship of Lord Balfour of Burleigh, had come to a unanimous decision in favour of the adoption of a policy of preference, and that resolution was agreed to, not only by people like himself, who had always been identified with that policy, but by Lord Balfour, by prominent Free Traders, and by representatives of labour. All parties combined to agree to that historic policy, but it must be remembered that it was a historic policy, because, although this country abandoned it for a short period, the Dominions had never done so. It was the system upon which the British Empire grew from the reign of Queen Mary up to modern times. The whole system which people had thought was so deeply rooted in English life had crumbled under the pressure of the war, and it was now necessary to consider on what system it should be built up again. The author had suggested some of the lines on which it should proceed. It was perfectly obvious that the old notions of a purely individualist organisation of economic life had been knocked to pieces by the war. He had not the least doubt that if, when the Imperial Conference took place, the British Government went before the Conference in no niggling spirit, but with the whole-hearted generous determination to adopt any method which would bring the Empire closer together and help to develop its resources, it would meet with the greatest degree of co-operation possible from the Colonial Premiers. It ought to be made clear to the whole world that they did mean definite things. They did not mean internationalism in trade or commerce, but they meant first and foremost the British Empire. In the second place they meant, he trusted, a permanent economic alliance between the British Empire and those who had fought with us. There was a good deal of talk in certain quarters about the extreme desirability of maintaining the old cosmopolitan relations. He trusted the country was not going to do anything of the kind. The theory that, by throwing our markets open to everybody peace would be guaranteed and prosperity secured, had been proved by the war to be incorrect. All that was done by pursuing a policy of that kind was to allow an aggressive Power to permeate our trade, commerce, and finance, and undermine the very existence of the Empire. There was nothing hostile, unfriendly, vicious, or aggressive in the attitude he suggested; but the Empire should, without any feeling, though in a quiet businesslike way, lay down as the principle of their action—the Empire first and all the time, then our Allies, and the other people where they could get in. If the Empire acted upon these principles he believed a great Western alliance would be formed between the British Empire, France, Italy, and our other Allies, and it would be impossible to measure what that would mean for civilisation. But it

must all rest upon the economic basis, and it must not be supposed for one moment that it was possible to substitute any policy which would dispense with the economic organisation of the resources of the Empire. Self-government was no good unless the self-governing body controlled its fiscal and economic policy; and, provided that was done, the other institutions would grow and flourish. It was unnecessary at the moment to think too much about the future, because the policy of the future would be largely made in the furnace of the war. He hoped the organisation and mobilisation of our Imperial resources would not be delayed until peace was declared, but that they would be carried out at once for the purpose of carrying on the war to a successful conclusion.

MR. H. WILSON FOX, M.P., hoped the people of the country would approach the subject with such determination that they would not allow the accomplishment of the great end in view to be prevented because all sorts of difficulties were in the way. Many of the difficulties were academic, resulting from a system which had become crystallised. That system must not be allowed to interfere; it must be remodelled or, if it could not be remodelled, swept away and a new organisation created in its place. One of the difficulties connected with the questions dealt with by the author was that of Treasury and Parliamentary control. Nobody could deny that there must be some measure of Parliamentary control over expenditure, but he thought it was necessary to divest our minds of the idea that the control must be exercised through the Treasury in the old way, because, if it was, the new organisation would be strangled from its birth by bonds of red tape. It was necessary to find new methods of Parliamentary control for checking the work of the great organisations to be set up, and he thought the solution was to be found on the lines of associating the great Dominions with the work. For instance, if the Imperial Board of Development was selected by a future Imperial Council or Parliament, then the question of patronage by the Government of the day would be largely swept aside. Similarly, if the control of individual branches of the organisation were entrusted to statutory authorities which had the right to spend public money, under the supervision of commercial auditors responsible to Parliament, many of the difficulties of the present system would be got rid of. If the country was satisfied that the work should be done it was its business to get over the difficulties raised, and for that purpose he hoped those present would support the view that at the earliest possible moment a Committee should be appointed by the Government with the express object of devising means whereby the aims in view could be successfully carried out.

MR. MORETON FREWEN said the United States was at the present day confronted with a most appalling food problem. He had always been an avowed Protectionist, but the United States had pushed manufacturing protection to such an extent that they had upset the natural balance that should exist in a country between agrarian and industrial conditions, and they had so congested their people in towns for the purpose of their industrial system that it was impossible any longer for the farmers of the United States to supply the food that was required. As a result of the demands made by the great industrial centres in the United States, the food of the Empire was being sent to the States, and unless something radical was done to protect our food supplies he prophesied that in the next ten years the entire cattle trade of Ireland would go to New York. There had been an enormous growth in the value of land in Canada since 1878, and nothing would induce him to believe that the pressure of 100,000,000 people on the Continent of North America would not raise prairie values in the north-west, now perhaps one dollar an acre, to £20 an acre in the next twenty years. In 1913 the immigration of settlers, chiefly from the United States into Canada, was such that they took up in homesteads over seven million acres, and in that way Canada gave away property possessing a potential value of at least £150,000,000 sterling. The Empire Resources Committee was under a debt of obligation to the author for his suggestion that the fisheries of the Empire should be nationalised. In any scheme brought before the Board which it was hoped would be constituted, it was desirable in the first place to deal with an industry in which the return on capital was exceptionally large. In this country the gross yield on the £10,000,000 invested in the fisheries was more than £10,000,000 a year; while in Canada the gross yield was £7,000,000 a year on an invested capital of £5,000,000. In the United States also there was more than 100 per cent. gross return on the capital invested in fisheries. The capital of the British Isles was reckoned to be £14,000,000,000, and the gross return on that, excluding duplicate entries and imported raw material, was only 9 per cent., compared with more than 100 per cent. from our fisheries. He thought it was also fair that the State should be asked to encourage fisheries, because, while the individualist farmer cultivated his fields and reaped his own harvest, a very large part of the expenditure of money, both in the United States and Canada, on ocean fisheries was connected with operations such as hatching salmon and lobsters, and no individualist who was not a crazy altruist would hatch lobsters and turn them out in the ocean on the chance that he would benefit by their capture. The State must do those things. If cold-storage plants could be erected in every town and we took advantage of the mighty

harvest of the ocean to store during the months of abundance against the gales of winter, and were the State given a profit of, say, 1*d*. a lb. on the sales of fish, the consumption would be very largely increased.

Mr. A. M. Samuel said he did not look with apprehension upon the great debt that was being piled up as a result of the war. From an economic point of view it was simply a capital expenditure of £5,000,000,000 for the extension of national machinery, and as a business proposition it would pay if the sources of supply in the Empire were linked up. During the ten years before the war £500,000,000 was lost in limited liability schemes of a wild-cat character, and he thought such money in the future could be diverted to the development of national resources. He also suggested that the railways of India might be profitably extended. It was disastrous that this country had to depend on the United States for certain classes of cotton, and, as American requirements for cotton were growing, this country would find itself faced with an increasing shortage of supply. This could be adjusted by an increase of British-grown cotton. He also supported the suggestion that had been made with regard to fisheries, and thought that the Government might with advantage provide refrigerators for the storing of fish at every railway station throughout the country. Indian hides also should not in the future be sent to Hamburg or the United States to be tanned and come back to this country to be made up. He was totally against the principle of bringing only dead meat to the country, leaving the valuable hides and the offals to the foreigners.

The Hon. F. W. Young (Agent-General for South Australia) said the war had enabled the people of this country to appreciate how the British Empire controlled the assets of the world, and he hoped that would make us stronger in our attitude to all other nations in the future. With regard to the question of State assistance in the development of those assets, it was necessary to be careful not to bring the State too intimately into the matter. He still believed a great deal in the individual, and thought the proper way to work the scheme was that the suggested Empire Board should have as little as possible to do with the actual work of development, and still less to do with the profits. Human effort was limited by population, and by the extent to which individuals made use of their energy and abilities. People were already more or less engaged in development and production, and one of the problems of the future was to develop the energies of the people throughout the Empire to the utmost of their capacity. The war had brought classes together in a way that nothing else could have done; there was a greater disposition on the part of capital and on the part of labour to work together hand in hand, and in that way there would be a greater production in the future. He hoped that, as suggested, the central concern would get on very happily with all its employees, but it had not been proved that because a man was employed by his country he was any more contented or less likely to strike. Men appreciated that they were not only employees but voters, and, feeling the additional power, were prone to exercise it. In the newer countries it had been found necessary for the State to interfere to a certain extent by finding part of the initial expenditure involved and offering special inducements to men to go into new concerns, in the hope that ultimately those men would be successful, and in that way would help to build up the wealth of the country to which they belonged. If the Empire was to be developed as a whole, facilities must exist so that the people and the wealth of the Empire could pass freely from one part to the other without suffering any disabilities. Unfortunately, this condition did not exist at the present time. If a person in this country, with a view to developing the Imperial assets of Australia, invested money there, he had to pay income tax to the extent of 13*s*. in the £, because he paid income tax not only in this country but also in Australia. That grievance should be remedied. If the resources of the Empire were to be pooled, it should be possible for a man who had his wealth in any part of the Empire to transfer it to another part without having to pay income tax twice over.

The Hon. Sir John McCall (Agent-General for Tasmania), in proposing a hearty vote of thanks to Mr. Bigland for his paper, thought that one difficult question that might arise in connection with the scheme suggested was that the control that would be necessary over the large amount of capital involved must be something more than the present Imperial Government control; but no doubt it would be easily possible to solve that difficulty.

Mr. Byron Brenan, C.M.G., seconded the motion, which was carried unanimously, and Mr. Edward Dent having, on behalf of the Committee of the Colonial Section, thanked Mr. Hewins for presiding, the meeting terminated.

POTASH FROM ALUNITE.

It appears from a Bulletin recently issued by the United States Department of Agriculture that considerable interest is being evinced in processes for the recovery of potash and other products from alunite. This mineral is a hydrous sulphate of potash and alumina, and it occurs in important deposits both north and south-west of Marysvale, Utah.

Difficulty in effecting a complete separation of the potash after the ignition of the mineral has been experienced both in the laboratory and in factory practice; and since the material must be regarded as a relatively low-grade potash carrier, cheapness and efficiency in the extraction of the potash are essential to its successful commercial development.

Eleven samples of light-coloured alunite from the undeveloped but readily accessible area north of Marysvale were ignited at different temperatures and the residues subsequently leached with water. A temperature between 750° and 800° C. was found to be best for the complete extraction of the potash with the minimum amount of water. Temperatures above 800° C. caused a fixation of the potash, particularly where the samples contained much silica. An experiment to test the influence of fineness of grinding on the subsequent extraction of potash from alunite showed that nothing is to be gained by grinding the material finer than 60 mesh.

Since practically all of the constituents of high-grade alunite have their market in the East, it is suggested that it would prove more economical to ship the mineral east, taking advantage of the lower freight rate on raw material, than to manufacture the finished products near the mines. The freight charges even then, however, are so great as to leave a very narrow margin of profit on the products in normal times.

Copies of the Bulletin may be obtained at a cost of 5 cents each from the Government Printing Office, Washington, D.C.

BAY RUM INDUSTRY IN THE DANISH WEST INDIES.

The cultivation of the bay tree and the extraction of the oil from its leaves provides for the island of St. John, Danish West Indies, its most important industry; and the distillation of this oil and its subsequent manufacture into bay rum furnishes for the sister island of St. Thomas its only article of local manufacture and the most important of all its exports.

According to a report by the United States Vice-Consul at St. Thomas, approximately 4,000 quarts of bay oil are produced in St. John annually, the greater part of which is sent to St. Thomas, from which it is estimated there is manufactured for export purposes about 60,000 cases of 12 quart bottles each of bay rum. The St. Thomas bay rum, which is considered the best on the market, is sent to all parts of the world. The greater part, however, is exported to Jamaica and to Panama, whence it is transhipped to the countries on the west coast of South America.

The requirements for the extraction of the oil from the bay leaves, and its later manufacture into bay rum, are not of sufficient importance to warrant a special interest on the part of manufacturers of this class of machinery, inasmuch as the only important appliance for which there might be a very limited market would be a still that could extract a greater quantity of oil from the leaves than is obtained at present by the crude methods employed, and one that would automatically separate the oil from the water. For the bay rum that is exported from St. Thomas, the cases, bottles, etc., are all imported from the United States, with the exception of the corks, which come from Spain.

Although bay trees can be grown over the greater part of the island of St. John, only about 50 acres are devoted to its cultivation. The pickings of the first few years should yield about 25 lb. of leaves to a tree annually; but after the tree has reached its maturity at least 100 lb. can be counted on providing weather conditions are favourable. A bay tree reaches its maturity when about ten years of age, and under ordinary circumstances will continue to bear leaves for fifty, sixty and seventy years. According to the opinion of experienced growers, three pickings a year bring in the best yield and create conditions that favour the superior quality of the leaf.

Last summer bay leaves sold for ¾*d.* per lb., but in normal times the price is 1*d.* The price of the oil (18*s.* 9*d.* per quart) is considerably less than that ordinarily received, and because of the slack market in St. Thomas, where the oil is usually sent, and the failure to find buyers abroad, large quantities of the leaves are being allowed to go to waste. The retail price of bay rum in St. Thomas is 1*s.* a quart. No customs duty is levied on any article of export from these islands.

CORRESPONDENCE.

HENNA.

The following remarks on the botanical history of henna will, I feel, add to the interest of the extract given in the *Journal* of March 23rd from the Italian *Annali della R. Stazione Chimico-Agraria Sperimentale di Roma.*

Henna is the trade name of the *Lawsonia inermis* of Linnæus, the *L. alba* of Lamarck, commonly known as "the Egyptian Privet" and "the Jamaica Mignonette," a plant of the Natural Order Lythraceæ, or Willow-worts, of which the lovely "Purple Loosetrife" [the "Lysimachia" of Pliny] is the species best known to English people. It is said to be a native of Northern Africa, from whence it has spread into Palestine, Syria, and Persia, throughout India, and even into China, and *across the Atlantic* into the West Indies. It is the *gopher* of the Old Testament translated in our Authorised Version [Song of Solomon i. 14 camphire: "My beloved is to me as a cluster of

camphire in the vineyards of Engedi"—where it still abounds. It is the κύπρος of Dioscorides I. 24, and the "Cyprus in Egypt" of Pliny XII. 22 (51). It is mentioned by the earliest Arabic writers on the botanical drugs of the East, and by the earliest modern European botanical explorers and writers, as by Belonius and Rauwolf in the sixteenth century A.D. The Homeric phrase, "Rosy-fingered Ἠώς" [the Sanskrit *ushas*, "brightening," and Ushasa, "Aurora"] also is recognised as obviously referring to the almost universal use by the women of the East of henna for colouring the tips of their fingers. The young girls of China use it to paint a rosy stripe between their eyebrows. It is also used throughout the East to redden the beards of the men, and to paint the manes and tails of horses. It is used also as a medicine; the roots made into a poultice for sore, war-worn feet, and as an application to ulcers; and the powdered leaves internally in leprosy; but, so far as I have observed, with little efficacy. Its most interesting use is in burning the seeds as an incense to ward off evil spirits.

The word "Henna" is the Arabic *hinna*, in Persian *hina*, in modern Greek χίννα, its Arabic name being connected with the verb *hana*, "to become queen."

GEORGE BIRDWOOD.

NOTES ON BOOKS.

A SCHOOL RUSSIAN GRAMMAR. By E. G. Underwood. London: Blackie & Son, Ltd. 2s. 6d. net.

A PROGRESSIVE RUSSIAN COURSE. By P. M. Smirnoff. London: Blackie & Son, Ltd. 3s. 6d. net.

As a natural consequence of the closer relations between Great Britain and Russia, a remarkable stimulus has been given to the study of the Russian language in this country. Last year classes were established under the London County Council, and by independent institutions both in London and at various other centres throughout the country; and in one at least of the Scottish universities a holiday course in Russian was held for the first time for teachers. It is not very easy to obtain precise figures of the numbers of students of Russian in Great Britain; but the statistics of the examinations of the Royal Society of Arts may probably be regarded as a fairly sure indication of what is taking place generally in this direction. In order to encourage the study of Russian the Society has for nearly thirty years held examinations in this subject; but the number of entries had always been disappointingly small, and in 1915 no examinations were held. Last year, however, it was announced that they would be held again, and no fewer than 127 candidates entered their names.

One of the difficulties with which teachers of Russian had to contend last year was the absence of good grammars and text-books suitable for young English students, and there should be a considerable demand for the two volumes before us. Mr. Underwood sets out clearly the main outlines of Russian grammar, and one who has mastered the book should be able to read simple Russian. Mr. Smirnoff's "course" is divided into thirty lessons, with a supplement containing simple selections from Russian prose and verse, and he claims that a pupil who has carefully worked through the book should have a sufficient stock of words to carry on an ordinary conversation in Russian.

GENERAL NOTES.

RUSSIAN EXHIBITION.—An Exhibition, descriptive of the industries, art, literature and customs of Russia, will be held at the Grafton Galleries, Bond Street, W., during May. The object of the Exhibition is to give the English public an opportunity of learning about Russia, her people, art and literature, and to demonstrate the opportunities that exist for closer friendship and trading relations between England and Russia. For the benefit of all seeking information about Russia, a Commercial Intelligence Bureau will be opened under the direction of Baron Heyking. The proceeds of the Exhibition will be given to the Anglo-Russian Hospitals, which, during the past year, have done excellent work under the Russian Red Cross on different Russian fronts.

COTTON STANDARDS AVAILABLE FOR GROWERS.—In an attempt to produce a more exact classification of cotton in place of the approximations to grades now often employed in gin, street, and warehouse sales, the Office of Markets and Rural Organisation of the United States Department of Agriculture is co-operating with the States Relations Service of that Department in placing in the hands of county agents in the cotton-producing sections, sets of practical forms of the official cotton standards of the United States. The forms are furnished only after the agents have given satisfactory assurances that they will be kept in a place accessible to cotton growers, in the care of a competent custodian who does not profit directly from trading in cotton. Each set of the practical forms consists of the nine grades of white cotton. They remain the property of the United States Government. In arranging for the keeping of the standards in the counties, such agencies as banks, chambers of commerce, boards of trade, and stores whose proprietors do not trade in cotton have been approved. It is believed that the presence of a set of the practical forms in each county, where farmers may examine and become familiar with them, will be a valuable educative force in grading.

COTTON MACHINERY IN JAPAN.—According to an extract from the Japanese press, recently forwarded by H.M. Commercial Attaché at Yokohama, Japanese cotton-spinning companies have decided to investigate the possibility of using American machinery in their mills. Hitherto Japan has relied upon United Kingdom manufacturers for supplies of spinning machinery, in the use of which both her engineers and operatives have been trained. The extent of purchases in the United States already decided upon is estimated at 200,000 spindles, and delivery is expected within five or six months of placing orders. It is stated that difficulties in obtaining supplies from the United Kingdom are responsible for this development. Although this loss of business, as is suggested, is primarily due to the war, it should be an indication to British makers of this class of machinery that they are not indispensable in the Far Eastern markets, and that unless they are making adequate preparations to hold their own after the war, they will by no means have a field to themselves where hitherto they have thought themselves superior.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

APRIL 18. — HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance." SIR GEORGE THOMAS BEILBY, LL.D., F.R.S., of the Fuel Research Board, will preside.

APRIL 25.—SIR FRANCIS FOX, M.Inst.C.E., "Flour and Bread." CAPTAIN CHARLES BATHURST, M.P., Parliamentary Secretary, Ministry of Food, will preside.

MAY 2.—J. C. SHENSTONE, F.L.S., M.P.S., "Herb-growing in the British Empire: its Past, Present, and Future."

MAY 9.—PROFESSOR WILLIAM RIPPER, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

MAY 16.—SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

INDIAN SECTION.

At 4.30 p.m. :—

THURSDAY, APRIL 19.—R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products."

Date to be announced later :—

D. T. CHADWICK, I.C.S., "The Future of Indian Trade with Russia and France."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

MAY 1.—PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

HOWARD LECTURES.

Monday afternoons, at 4 p.m. :—

WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Cheap Iron Ore Supplies." Two Lectures. (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market.

April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 2...Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. R. Seligman and Mr. P. Williams, "Further Notes on the Action of Acetic Acid on Aluminium." 2. Mr. R. Brightman, "Nitrated Castor Oil."

Engineers, Society of, at the Geological Society, Burlington House, W, 5.30 p.m. Mr. A. M. Arter, "Ball Bearings."

Geographical Society, Burlington-gardens, W., 5.30 p.m. Captain A. J. A. Douglas, "Two Journeys in the High Atlas."

TUESDAY, APRIL 3...Röntgen Society, at the Cancer Hospital, Fulham-road, S.W., 8.15 p.m. Mr. G. Pearce, "The Future of the British X-Ray Industry."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7 p.m. Lecture by Professor E. Wilson.

(Scottish Section.) 207, Bath-street, Glasgow, 7.30 p.m. Mr. J. Shepherd, "Some Points in connection with Engineering Specifications."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Discussion on Mr. E. M. Lacey's paper, "The New Electric Power-house at Birchills, Walsall." 2. Messrs. P. V. O'Brien and J. Parr, "The Coolgardie Water-supply, Western Australia." 3. Mr. P. V. O'Brien, "Water-supply in the Interior of Western Australia."

Photographic Society, 35, Russell-square, W.C., 7 p.m.

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. A. Ezra, Lantern exhibition illustrating Big-Game Shooting in India. 2. Mr. R. H. Burne, "Notes on some of the Viscera of an Okapi. *Okapia johnstoni*."

Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m. Address on Canada, by Lord Shaughnessy.

WEDNESDAY, APRIL 4...Aeronautical Society of Great Britain, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. B. Young, "Magneto Electric Ignition on Aircraft."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. 1. Mr. V. B. Crowther Beynon, "Notes on Some Family Relics of the Jacobite Rebellion, 1745." 2. Dr. P. Nelson, "Some English Mediæval Embattled Alabasters."

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 30, 1917.

Journal of the Royal Society of Arts.

No. 3,359. VOL. LXV.

FRIDAY, APRIL 6, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, March 6th, 1917; Mr. A. D. STEEL-MAITLAND, M.P., Under-Secretary of State for the Colonies, in the chair.

THE CHAIRMAN, in introducing the reader of the paper, said that M. Horn was not only well known in business circles in this country in connection with the Belgian Congo, but those interested in missionary enterprise had reason to be familiar with his work and to be glad of it. The meeting was also favoured with the presence of M. Renkin, the Colonial Minister of the Belgian Government, to whom he was sure they would accord the heartiest welcome.

The paper read was—

THE ECONOMIC DEVELOPMENT OF THE BELGIAN CONGO.

By M. HORN, LL.D. (Brussels).

Few questions to-day occupy a more prominent position in our minds than those relating to the economic resources of the nations between whom the present war has established new or closer ties.

A fresh and acute interest has arisen as to the commodities which these nations are, or will in the near future be, in a position to produce for their own and each other's requirements, and as to the outlet which they will afford each other respectively for their surplus production.

Although the contribution which the Belgian Congo can offer, both as a source of supply and as a market, is as yet comparatively small, it may be found of sufficient importance to be taken into account in the consideration of these great problems.

It is for this reason, I take it, that the Council of the Royal Society of Arts, when they did me the honour of requesting me to read a paper on the Belgian Congo, suggested that my subject should be the economic possibilities of that Colony.

I shall, therefore, this afternoon refrain from making more than a passing reference to the political history and administrative organisation of the Belgian possession. Notwithstanding the place which the war occupies in our thoughts, I shall say nothing of the part which it has been the duty, privilege and glory of the Congo Army to take in repulsing the enemy's unwarranted aggression, and evicting him from the Cameroons and from German East Africa.

Besides, the economic development of a country of the magnitude of the Belgian Congo affords in itself an over-abundant topic for the brief space of a paper.

The size of this Colony, exceeding 900,000 square miles, is approximately equal to the combined area of the British Isles, Belgium, France, Portugal, Spain, Germany, Switzerland, and Italy, and it affords a variety of natural conditions and resources hardly less great than that which we all know to exist in the last-mentioned group of countries.

A considerable number of volumes and pamphlets have been written on the Congo, and from these and from the verbal reports of men who have been "on the spot," it would be easy to make a selection of the most conflicting opinions.

Nobody can boast of having actually seen and of thoroughly knowing more than a small portion of the Colony. Officials, missionaries, and traders, whose sphere of action is necessarily restricted, have the natural propensity of judging the whole of this vast country by the particular regions with which they have become familiar, and of which perhaps the least attractive, viz. the Lower Congo, is the most generally known. Even the most active traveller can only have visited strips of land alongside of a limited number of highways and tracks. Moreover, is it not a general rule that we can only find what

we are seeking for? It is only too easy to pass beside even unhidden riches without suspecting their existence. Of course, personal achievements and disappointments, joys and worries, as well as the state of our health, to a large extent influence our estimate of the things we observe.

Those who are in the best position to form an independent opinion based not only on direct experience, but also on information gathered from numerous and varied sources, will, I think, agree that, in a general way, a more accurate impression is conveyed by Stanley's writings than by the great majority of later publications.

Stanley, let us remember, had travelled very slowly right across the country, making observations and drawing inferences, with an unprejudiced and marvellously perspective mind. As is frequent with men blessed with the gift of imagination, he appears to have underestimated the time which would be required for the possibilities he had recognised to become realities. But fresh evidence is continuously accruing in support of the conclusion at which he arrived forty-two years ago, viz., that this area, of which he was the principal discoverer, "excels all other known lands for the number and variety of precious gifts with which Nature has endowed it."

It may be assumed that almost every kind of mineral wealth will ultimately be discovered in some part or other of the Colony.

Amongst those of commercial interest the best known at present are the copper and tin deposits of Southern Katanga, the goldfields of the north-eastern districts, the coal-seams of the Lukuga (Tanganyika district), the diamondiferous alluvia of the Upper Kasai, and the conspicuously abundant resources of iron ore of the Uele and Ituri.

Elsewhere there are definite indications of copper, gold, lead, diamonds and oil, and there can be no doubt that more widespread and fuller prospecting will lead to many fresh discoveries of mineral wealth in the enormous mountainous crescent which encircles the Congo basin.

There is everywhere abundant material for building and road-making. In all probability kaolin will be some day exported from the coastal region. A fear which obtained until recently that there might be a deficiency of lime for the manufacture of cement and for agricultural purposes has since been dispelled.

To most minds, perhaps, the mention of the Congo will conjure up glorious visions o primeval tropical forests. Although large stretches of such forests are less frequent than may be commonly believed, yet the exuberance of the natural vegetation can hardly be exaggerated. The Congo contains practically inexhaustible stores of wood and fibrous material—fibres suitable for the manufacture of bags, ropes, and brushes; wood in abundance for fuel and timber, ebony and mahogany, besides tanning and dyewood.

Need I mention the rubber trees and vines, the reserves of which Nature indefatigably replenishes?

Unlimited supplies of gum copal are embedded in the marshy regions of the central districts.

Perhaps the most valuable assets amongst this vegetable wealth are the oil-bearing plants, the most conspicuous of which is the oil palm (*Elæis guineensis*), scattered by tens of millions in clusters, groves and forests, over nearly the whole of the Colony. In this connection it may be of interest to note that an opinion current in British West Africa, and which may be well founded there, viz. that the oil palm will not thrive beyond a comparatively small distance from the coast, by no means applies to the Belgian Congo, where luxuriant palm forests are found more than eight hundred miles from the sea border. A further natural advantage of the Congo worthy of mention is that, in the equatorial zone, amongst other plants the oil palm yields a continuous supply of fruit all through the year.

Elephants appear to be as numerous as ever, notwithstanding all the hunting to which they have for many years been subjected, and the statistics show no decrease in the output of ivory.

For the big-game hunter the Congo affords a most attractive and varied field.

Beeswax, perhaps less plentiful than in other colonies, is offered for sale on the native markets, notably in the Upper Kasai and Upper Lulua regions.

Large quantities of African silk (anaphe nests) are reported in the central and north-eastern districts.

Of all the potentialities of the Congo I should regard as most valuable its possibilities for agricultural development.

It is, I believe, by the production of agricultural commodities more than in any other direction, however important, that this Colony will ultimately be called upon to contribute to the well-being of the world.

Every kind of tropical or semi-tropical produce will prosper in the Congo, which is richly endowed with the two essential factors —heat and moisture.

Looking from east to west, we first find the hot and rather insalubrious coastal region less than eighty miles wide. Then, crossing the range of Crystal Mountains over heights of 1,500 ft. and more, we reach the Stanley Pool (660 ft.). Beyond this point a fan-shaped plateau rises gradually southward and eastward, with an increasingly temperate climate. The altitude of the southern country ranges from 800 ft. to 5,000 ft. Snow-covered peaks of over 18,000 ft. are comprised in the eastern crest.

In the equatorial zone the rainfall (60 in. to 80 in.) is evenly distributed all through the year, and the temperature shows but slight variations. Seasons become more accentuated as we get farther from the equator. In Upper Katanga, for instance, the rainy season in 1915 lasted seven months (seven to twenty-nine days of rain per month), and the dry season five months (four to seven days of rain per month), the total rainfall amounting to 52 in., and the temperature varied from 38·8° F. (July minimum) to 92·8° F. (November maximum).

The soil is by no means uniformly fertile. Whilst there are many tracks of rich loam, notably in the volcanic regions west of the Great Lakes, sandy soils are predominant. Considerable areas have been impoverished by the primitive methods of cultivation practised for generations by the natives; and even in forest land the top soil is frequently only 20 in. deep.

In view of these circumstances misgivings have found utterance in respect of the agricultural possibilities of the country. But the lightness of the soil renders it easily workable — and is there any chemical deficiency which human science and industry cannot overcome?

None should be less dismayed by difficulties of this kind than the people of Flanders, who have carried their cultivations to within a few yards of the sea.

And does not the fact that many of the most valuable plants and trees are indigenous and thrive luxuriantly in their natural state in itself suffice to dispel all doubts as to the response they will give to the care of the planter? True, there is a good deal of poor land, but before the necessity can arise to turn this to account, millions of acres which require little or very little improvement will be found available for native and European enterprise, far in excess of what we could ever hope to see fallowed or planted in the near future.

Into this mass of natural wealth Providence has thrown an incomparable system of navigable highways—the mighty Congo River and its tributaries.

The majority of these streams, of comparatively recent formation, are intersected by rapids in their higher reaches, and the mountainous girdle of the Congo basin traversing the main river in its last stretch causes those fateful breaks which, until the last half century, shut off Central Africa from the outside world.

Need I point out that the rapids, together with a multitude of mountain torrents, constitute inestimable reserves of motive power, and that between the broken sections lie over 9,000 miles of navigable water?

All the natural wealth of the country would be of no avail without human energy to turn it to account.

The native population of the Colony may be put down at fifteen millions (estimates vary from twelve to eighteen millions). The census operations have not yet extended to the more remote areas, and even in other parts they are hampered by a well-founded suspicion that registration entails Government supervision. Who could blame the native for prefer ing that the administration should remain in ignorance of his existence as a possible taxpayer, and should continue to be unable to trace his movements and the whereabouts of his wives and children?

As a consequence of recent legislative measures (Royal Decree of November 16th, 1916) a definite register will probably be available a couple of years hence.

It has often been asserted that the territories which to-day form the Belgian Congo are less populated than when they first came under European rule. This opinion appears to be generally based on the fact that certain areas, which at one time were found to be well inhabited, are to-day almost deserted. It should, however, be borne in mind that many Central African tribes were, until recently, and to some extent are yet (*e.g.* in the southern parts of the Kwango and Kasai districts), habitually nomadic; that their exhausting agricultural methods entailed in particular the abandonment of the most extensively cultivated tracts of land; that, moreover, disease, as well as a desire to avoid

the white man, have frequently caused the native to withdraw from the main thoroughfares into the interior.

So much is certain: European rule has freed the aborigines of the Congo from the Arab slave raids and from inter-tribal warfare. Poison-ordeals, cannibalism, and other causes of violent death have been practically stamped out; the slave traffic in the interior will soon be extinct; hemp-smoking and other vices are severely repressed, and polygamy is being gradually reduced. All of these circumstances are obviously or presumptively conducive to an increase of population.

On the other hand, the rapid spread of sleeping-sickness and venereal diseases has caused terrible havoc; in some regions porterage and requisitions have been obtained at the cost of many lives; and it appears to be a deplorable but inevitable fact, also observed amongst other primitive races, that the fresh conditions of life created by the contact, or even by the mere presence of the white man, frequently produce a state of nervous tension which burdens the death-roll and decreases the birth-rate.

On balance, there is reason to assume that the unfavourable elements have been so far predominant, but that a turn of the tide has now been reached. The ravages of sleeping-sickness are becoming less severe, thanks largely to the indefatigable efforts of medical officers and missionaries, and to administrative measures in which the native communities have been called upon to co-operate. Mechanical means of transport are replacing porterage, of which, moreover, the hardships have been very much lessened. The natives are becoming gradually accustomed to contact with the European; and better conditions of food, housing and clothing, together with more provident and industrious habits, are bound to improve the physique and the power of resistance of new generations.

We may, therefore, in the near future, confidently expect a steady increase of the native population.

At fifteen millions, its average density works out at about 39 acres per head. Allowance must, of course, be made for waterways, swamps, and other tracts which cannot be brought under cultivation, and for such areas of comparatively small extent which a e only suited for pasturing purposes. Yet it appears manifest that the amount of forest and agricultural land available, to say nothing of the mineral resources of the country, remains enormously in excess of what the native population could possibly develop without the assistance of European organisation, science and equipment.

As already mentioned, the climatic conditions of the Colony vary widely according to the altitude of the different regions. Certain parts, notably the marvellous country west of Lake Albert and of Lake Edward, may be fairly compared with the Riviera. The Upper Katanga and Upper Kasai can properly be described as a white man's country; and there is, so to speak, no portion of the Congo in which the European could not reside for a considerable number of consecutive years. Precautionary habits and sanitary improvements will gradually eliminate those malarial diseases which constitute the principal, and I may say the only serious, danger which threatens the European settler. More comfortable housing and a greater variety of fresh diet will, moreover, increase his power of resistance, and as the white population increases in numbers he will find better opportunities for the education of his children, and the stimulus of social intercourse will replace the depressing effects of isolation.

At the last complete census (1912) the white residents numbered 5,465, of which 3,307 (60·5 per cent.) were Belgians and 505 (9·25 per cent.) British. I am sorry I am unable to give a more recent return. A certain decrease in the figure mentioned would probably be shown to-day; since the war a number of officials and others have joined the Belgian and British colours, principally in East Africa, and the citizens of enemy countries and representatives of enemy trading concerns have left the country. On the other hand, the number of European children is increasing; in 1915 there were ninety-six births. Exclusive of the Kivu district and of the officers and men on active service, the white population amounted to 5,289 on January 1st, 1915.

There is a growing influx of Arab and Hindu traders and craftsmen from the Sudan and from Uganda. In my opinion this should be welcomed: the adequate development of the Colony requires that the energies of the aboriginal population should be lea ened by the influence of more advanced races, and I believe that white emigration alone cannot fulfil this end.

From an economic point of view the aborigines are of unequal value. Ethnically they comprise such different types as the pygmies of the Aruwimi forests, and the long-legged plain-dwellers of the Upper Uele. There are tribes which can be specifically described as hunters, fishermen, pastors, and farmers. Some have

attained a considerable proficiency in the arts of weaving and pottery, and in iron and copper work; others show hardly any traces of even the most rudimentary civilisation. If vice and disease have brought certain races to a deplorable state of degeneration, the majority are muscular and healthy, or will speedily become so when they are taught to increase their supplies of vegetable and animal food and enabled to add to their diet a sufficiency of salt.

There is abundant proof that a very large section of the Congo natives show remarkable aptitude for learning the handicrafts of the white man. Some are already rendering valuable services as mechanics, engine-drivers, clerks, interpreters, typists, compositors, and telegraph operators. In the recent campaigns the native troops, drawn from various regions, have almost invariably shown the highest discipline and valour.

Although with few exceptions these peoples are peaceable and tractable, yet European enterprise in dealing with them finds itself frequently hampered by difficulties arising from their domestic organisation and the modesty of their wants.

European industrial and agricultural undertakings necessitate the regular employment of trained and more or less skilled workmen. The use of female labour for tasks which require physical strength is abhorrent to the civilised mind.

Now, generally speaking, the Congo native has from time immemorial been accustomed to throw on his women folk the burden of heavy work other than clearing, and he has a strong abhorrence to disciplined exercise for any protracted time. Moreover, where, as is the case almost in every part of the Congo, it has been the habit of each family or group of families to cultivate severally all produce required for the sustenance of its members, the labourer engaged in European employ will naturally feel a strong desire to leave his employer in order to take part in the selection and clearing of the patch on which the family crop is to be grown.

It has been contended that it should be one of the duties of the State towards the aborigines of a new country to avoid the creation of a salaried class. But economic progress would hardly be conceivable without specialisation, and a body of wage-earners will call forth a body of prosperous farmers.

As regards the difficulties arising from the small needs of the native, we must consider that in the less accessible parts of the Colony his desire for imported goods is practically limited to a few yards of cloth and a few bags of salt for personal use or for the purchase of wives. The necessity of obtaining a small amount of cash to meet the demands of the tax-collector is often his only additional inducement to seek temporary employment, or to offer for sale a modicum of produce, fish or live stock. This would appear to justify the paradox that with such primitive people a rise of wage or price would tend to decrease the supply.

However, emulation and education are rapidly creating fresh needs, which, stimulated by the traders' tempting offers, afford new openings for trade and a larger supply of steady labour.

Thus will these invaluable reserves of human energy gradually develop their productive power.

It is, I am convinced, to the best interests of the aborigines, as well as of humanity generally, that the dormant wealth of the Congo should be turned to account. For this the capital and methods of European enterprise are as essential as the co-operation of the natives. I therefore feel strongly that, although the aborigines may indisputably have a first claim to the resources of their ancestral land, nevertheless part of these resources should be placed at the disposal of the white man in order to attract, secure, and remunerate his ventures. Without this an abundance of land, forests, and minerals would remain unexploited at least for an indefinite number of years.

But, however much the outer world may have a right to share in the products of the Congo in fair exchange for goods supplied and capital invested—Belgium being, perhaps, allowed a privileged title to such returns as a reward for the special services she is rendering to her Colony—I think I may say that the Belgian Government regard it as their fundamental duty to administer the Congo for the benefit of the Congo—*i.e.* for the prosperity of its inhabitants, amongst whom the natives constitute the enormous majority.

After this, I fear, rather superficial survey of the natural gifts of the Colony, let us rapidly go over what has been done to develop its latent resources and summarise the results so far achieved.

The authority of the State is to-day so well established that the trader and even the tax-collector can safely travel unarmed and unescorted almost anywhere throughout the Colony. During this war the natives have given most gratifying proof of their loyalty to King Albert

and of their attachment to Belgian rule. The townships and minor State posts number 487.

The present administrative organisation is based on that which the genius of King Leopold conceived and brought into being with astounding celerity. But it has been remodelled in many respects.

Thus, for instance, with a view to expedite the occupation and opening up of the country, the late King, Sovereign of the Congo Free State, whose personal means were insufficient to cover the requisite expenditure, in some instances granted administrative powers to private companies. But the combination of commercial interests and executive powers in the same hands is fraught with dangers to which the Belgian Government, as the Colonial Minister on a recent occasion has publicly reasserted, are resolved never again to expose the peoples placed under their care. The fundamental law ("Colonial Charter") of the Colony, which came into force when Belgium took over the sovereignty of the Free State (November 15th, 1908), expressly precludes all delegation of executive authority to private individuals or corporations. It stipulates, moreover, that none (whether native or non-native) shall be compelled to work on behalf or for the benefit of private interests.

By a Royal Decree, signed on the eve of the war (July 28th, 1914), the territory of the Colony is divided into four provinces—viz. the Congo-Kasai, Equator, Oriental, and Katanga Provinces, of which the chief cities are respectively Kinshasa, Coquilhatville, Stanleyville, and Elisabethville.

The executive head of each province is a Vice-Governor, assisted by a complete and distinct staff of officials.

The Vice-Governors are subordinate to the Governor-General, whose present residence is Boma, and who is, in the Colony, the representative of the King and supreme head of the whole civil and military administration.

It should be mentioned that the final organisation of the two first-named Vice-Governments has been delayed in consequence of the war.

The unit of administration is the district, in which the District Commissioner is the sole authority and has at his disposal a number of financial, technical, medical, agricultural and military officers. The district is divided into territories, the territorial administrators acting under the direct control of the District Commissioner. The districts, of which there are twenty-two, comprised in the provinces already referred to, have all been organised in their present limits from 1912 to 1915.

In the delimitation of these territories the native tribal divisions have, so far as possible, been taken into account. The aboriginal population is being grouped into chiefdoms and sub-chiefdoms, the greatest care being taken to establish the authority of those individuals who, according to native custom, are entitled thereto. More than 4,000 chiefdoms have already been organised. These communities are called upon to co-operate in administrative measures directly beneficial to themselves—such as road-making and protective clearing against sleeping-sickness—within the limits of their own chiefdom. Their chiefs exercise such traditional powers as civilisation can tolerate, and act as intermediaries between their subjects and the administration.

At the end of 1914 a force of 1,800 native policemen and nearly 18,000 native soldiers, commanded by European officers and non-commissioned officers, was employed or held in readiness for the maintenance of public peace in the Colony. Recent events have demonstrated the value of these effectives, but that they were greatly in excess of the requirements for which they were intended; although a large proportion of this force has been on active service "abroad," its absence has not given rise or led to local unrest.

The judicial staff of the Congo, comprising seventy-nine judges and public prosecutors, all professional legal men, may seem abnormally large as compared with that of other Colonies. But public opinion in Belgium is not prepared to admit that an administrative officer should be allowed more powers than a police magistrate. The absolute independence which the judicial body enjoys in the Congo with regard to the executive constitutes, I believe, a valuable, if perhaps an exaggerated, safeguard for the white as well as for the native population.

The whole of the country is open to missionary effort of every denomination. There is complete freedom of creed and teaching. The number of mission stations already exceeds 160, in addition to which several hundred native assistants are spreading the principles of Christianity and the rudiments of all European learning. It is estimated that about half a million children are at present receiving religious instruction. Three special schools have been established for chiefs' sons, and one for half-caste children, of whom there are about 600 in the Congo. One Belgian mission, that of the

Scheut Fathers, has to it credit no less than fifty schools and twenty orphanages. The State is initiating, or is subsidising, several schools for the training of clerks and artisans, notably at Boma, Buta, Lusambo, Stanleyville, and Elisabethville. In other localities private enterprise is encouraging similar teaching, and it may be confidently hoped that within a few years the supply of trained native employees and craftsmen will be sufficient to meet the growing local demand. Besides the benefits accruing to the native community by the advancement of some of its members, the services of educated black men of local origin will appreciably reduce the working expenses of European enterprise in the Congo.

To mention other measures which are destined to further relations between the white and native elements, markets under Government supervision have been organised in the majority of the territories. The officials responsible have strict orders to prevent fraud and illegality, but not otherwise to intervene in the transactions effected.

At Elisabethville, a labour exchange, on the South African model, is working satisfactorily.

Thanks largely to the munificence of King Albert and his Queen, there are now ten hospitals in the Colony, besides a number of lazarets. Provision is made for 101 State doctors; but military necessities have for the time being reduced this staff considerably below its full complement. There are a few private practitioners, and five of the principal companies have engaged doctors for their employees and labourers.

The medical facilities thus provided would be superabundant if the white residents alone were to be considered. But it would be quite inadequate to the needs of the native population were it not for the indefatigable assistance of the missionaries, of whom some are qualified doctors.

The natives, even in the more remote regions, are gradually overcoming their diffidence towards unaccustomed methods of treatment, and beginning to recognise the utility of the steps taken to arrest the ravages of sleeping sickness.

To complete these remarks, I must mention three legislative measures which contribute to the safety and health of the population.

In accordance with the stipulations of the Brussels Conference (1890), stringent limitations have been placed on the import of, and traffic in, fire-arms. The consequent difficulties which the natives sometimes encounter in the protection of their crops against elephants and other wild animals must be regarded as a lesser evil as compared with the dangers which might arise if they were in possession of modern weapons.

The terrible vice of hemp-smoking has, to a large extent, been stamped out, thanks to a systematic destruction of the weed.

Finally, the liquor traffic is subjected to restrictions, of which the principles were laid down at the same Brussels Conference.

The legislation on the subject, which until recently did not apply to the coastal region and has been several times revised, to-day applies to the whole of the Colony, and is as follows:—

"No native may import, or have in his possession, intoxicating liquors of more than 8 degrees proof, nor may a white man sell or give such liquors to the native.

"The white man can obtain an 'alcohol ticket' for 3 litres (two-thirds of a gallon) per month of liquor exceeding 22 degrees; but is limited to this allowance."

By this policy the Congo Administration has deprived itself of what might potentially constitute a principal source of revenue.

But although the consumption of highly fermented palm wine by natives to some extent nullifies the beneficial effects of this "sacrifice," the Belgian Administration has shown its firm intention to establish further limitations rather than to abandon this policy, the initiation of which is to the credit of the Congo Free State.

The dangers, hardships and discomforts which early pioneers had to encounter have everywhere been greatly lessened, and in many parts have disappeared. The Congo is no longer the land of peril and renunciation which attracted only the boldest and most self-denying, nor is it the last resort of social failures.

Throughout the Colony European commodities are easily obtainable; there is an ample supply of imported and locally-produced food. Comfortable and sanitary houses are rapidly replacing the old mud hutments and corrugated iron buildings. In the main centres of the Lower Congo and Katanga modern hotels have sprung up. Railways and steamers render travelling between the principal townships commodious. To-day the death-rate from natural causes amongst the European population is well below 2 per cent. per annum; a protracted stay in the Congo entails little more than ordinary risks. and a few months' visit may be regarded as a pleasure trip even for a white lady.

Considerable efforts have been made by the Government with a view to a better knowledge of the country's resources.

Scientific missions have been sent out for almost every branch of research. In this connection, it is to be hoped that the valuable and irreplaceable collections of the Congo Museum at Tervueren, near Brussels, will be found intact at the liberation of that city, although the loss of documents which were left at the offices of the Ministry of Colonies is to be feared.

Needless to say, all information of scientific or commercial interest in the possession of the Government is at the free disposal of the public.

Agricultural research has been thoroughly organised within the last few years. The Botanical Gardens at Eala cover 500 acres. Several mycological, bacteriological, entomological and agrilogi al laboratories have been established, and there are at present twenty experimental stations and farms. At one of the latter, at Api (Uele), the possibility of taming the African elephant for domestic use is being patiently tested, and not without success.

I should perhaps mention that these experimental cultivations and farms are undertaken without any view to profit, *i.e.* solely for the guidance and benefit of native and European enterprise. Seeds and live stock can be obtained, in many cases gratis, from these stations, to which are attached agricultural experts whose task it is to visit the surrounding district and give advice and assistance to natives and settlers.

The system of plantations for revenue purposes which the Free State Government had established on a large scale is now definitely abandoned. As soon as an agricultural experiment can be regarded as conclusive, and the station is no longer required for the distribution of seeds or the raising of breeding stock, the land and buildings are put up for sale or given over to the natives. Eight of the twenty stations referred to are at the present moment for sale, while new experiments are being prepared in other regions.

But the most effective way of opening up the country for investigation and trade is, of course, by development of the means of communication.

On the abnormally small ocean front which has been allotted to the Congo in consequence of the historical claims of Portugal, there is only one port, that of Banana, at the mouth of the river. But ocean-going vessels ascend the huge stream up to Matadi, close to where—100 miles from its mouth—its course is interrupted by the first rapids. The swiftness of the current in the "Devil's Cauldron," just below the latter harbour, renders it difficult of access to steamers of less than twelve knots. An additional port will shortly be established at Ango-Ango, three miles lower down.

A little more than half-way up this stretch is the port of Boma, which serves as an outlet for the produce of the Mayumbe district.

In 1914, 312,344 tons were cleared at Banana; 265,226 tons at Boma, and 133,509 tons at Matadi.

The regular services established between these ports and Europe are that of the Company Belge Maritime du Congo, which in normal times goes to Antwerp and at present to Hull, and that of the French Chargeurs Réunis, going normally to Havre and at present to Bordeaux. Amongst the occasional callers I should name the Elder Dempster, Empreza Nacional, and Bromport liners.

As regards the gigantic system of waterways in the Upper Congo, these rivers are, generally speaking, comparatively shallow in consequence of their unusual breadth. (The main river towards the summit of its curve attains a width of twenty miles.) In consequence the steamers supplying the Upper Congo do not as a rule exceed a 3 ft. draught, and are usually of the stern-wheel or tunnel-screw type. Interesting experiments are in progress with motor-propelled "gliders" as a means of rapid communication.

Sandbanks and snags render navigation dangerous at night and often cause considerable delay. An active hydrographic survey service has drawn up charts and is marking out the most favourable channels and carrying out dredging operations with a view to remedying these inconveniences.

Wood is the fuel generally employed, and State or native wooding-stations are established at regular intervals along the main course. The use of petroleum would mean a saving of time and of cargo space. These considerations had, shortly before the war, induced a company to lay down a pipe-line between Matadi and Stanley Pool, but the abnormal conditions of the oil market have delayed a fair comparison of the respective merits of the two modes of fuelling.

There are at present on the Upper Congo about one hundred steamers, of which forty-five are State-owned or State-controlled, in addition to a number of barges and whale-boats. The aggregate carrying capacity of this river fleet amounts to about 9,000 tons.

No licen e is required to put ships on the Congo or on any of its tributaries, nor for the

establishment of goods or passenger services on these rivers. Navigation on the Congo is entirely free.

The former Government had placed private shipping at a disadvantage by decreeing a very heavy tax on steamers, based on their assumed consumption, for fuelling purposes, of wood from domanial forests. One of the first acts of the Belgian Administration was to reduce this tax, which to-day stands at a quite nominal figure.

Thanks to the State-owned fleet, not only are freights in the Upper Congo maintained at a very low level, but the small trader is afforded the same facilities which more powerful firms and their associated companies derive from the private ownership of steamers.

Amongst the interior ports by far the most important is that of Leopoldville-Kinshasa, at the gateway of the Upper Congo. The bustling activity of this twin township—rapidly growing into one—of its extensive wharves, store-houses and shipyards, cannot be witnessed without leaving behind a convincing impression of the Colony's vitality.

The three comparatively short sections on which the course of the main river is interrupted by rapids have been supplemented by railroads.

At the very foundation of the Congo Free State the urgent necessity of a railway to connect the Upper Congo with the ocean was recognised as essential to the success of King Leopold's venture. Without this connection nothing but the most valuable produce could be exported, and that only by the costly and painful means of human carriers over a mountainous country. Animal transport had been tested and had proved a failure.

Begun in 1893 the Congo Railway was completed, despite many difficulties, within six years. For its inception and achievement the Colony owes a debt of gratitude to the inspiring energy of the late General Thys. Well built and well equipped, this narrow-gauge line (27.8 in.) of 250 miles—which has cost, including accessory buildings, about three and a half millions sterling—has so far sufficed to deal with the traffic of the Upper Congo and of the adjoining districts of French Equatorial Africa. But the time is close at hand when, without extensive constructional improvements, it will be quite inadequate to convey towards the ocean the growing flow of heavy produce.

Practical means of transport being established between the seaports and the waterways above the first group of rapids, a magnificent reach of the main river, twelve hundred miles in length, as well as the principal tributaries, were rendered accessible to commerce.

But in order that the whole of the great semi-circular high road which Nature has traced through this country might be laid open to traffic by steamship or rail, the Stanley Falls and a further stretch of rapids remain to be negotiated. The railway by which these obstacles have been overcome was completed in 1900, and comprises two sections—viz., Stanleyville-Ponthierville (83 miles) and Kindu-Kongolo (222 miles). Stern-wheelers of 250 tons ply on the intermediate water and up to the terminus of the navigable Congo, Bukama, 2,200 miles from the mouth of the river.

The natural outlet of the Colony towards the Atlantic having been thus improved, attention was turned to the means of connecting this channel of communication with the Indian Ocean and the South African railway system.

Whilst the administration of German East Africa was actively pushing forward the line from Dar-es-Salam *viâ* Tabora to Ujiji-Kigoma with a view to commercial and, perhaps, other penetration into Northern Katanga, a railway (169 miles) was placed under construction on the Belgian side of Lake Tanganyika, starting from Kabalo and reaching the lake at Kalemie, somewhat south of the township of Albertville. This line, which was completed towards the end of 1915, has rendered conspicuous service during the present war. It was designed mainly to open up a very promising coal and tin country where successful mining operations are already in progress.

With a view to avoid transhipment to Kabalo and Kongolo, a railway connection will, no doubt, in the near future be established alongside the navigable river between these two points, which are hardly 40 miles apart.

It is now possible to travel from the Pacific to the Atlantic right across Central Africa from Dar-es-Salam *viâ* Stanleyville to Banana within the space of a month.

Elisabethville, the capital of the Katanga province, still had to be linked up with Boma, the capital of the Colony, and the discovery of the stupendous copper deposits north of the first-named locality warranted an additional more rapid and, perhaps, more convenient communication with the ocean.

In 1909, after five years of preliminary survey and as soon as all doubt was dispelled as to the extension of the Rhodesian line to the Congo frontier, the construction of a railway between

the British terminus and Bukama was definitely decided upon. The work has been carried on from both sides simultaneously, and, were it not for the present shortage of rail plant, would by this time have been completed. As it is, nothing is required to connect the two finished sections (50 miles from Bukama and 370 miles from Sakania on the Rhodesian frontier) but the laying down of sleepers and rails on a stretch of 50 miles, and an overland route between the Lower Congo and Cape Town will be thus established.

I have only one other railway to mention —viz., the narrow-gauge (24 in.) line of the Mayumbe. This leads from Boma due north through prosperous cocoa plantations and plentiful palm groves to Tshela on the Lubudi, an affluent of the Shiloango (85 miles). The line will shortly be extended to this river, with which it will then compete for the export of agricultural produce from a comparatively small but thickly-populated region.

The aggregate length of fully-equipped public railways to-day stands at 1,229 miles, of which more than two-thirds (851 miles) have been constructed in the last eight years—*i.e.* since Belgium took over the administration of the Congo.

This, undoubtedly, is a record to be proud of. But a great deal remains to be achieved.

The north-eastern districts and at the opposite corner of the Colony, the southern regions of the Kwango and Kasai districts, in which there is little navigable water, must be provided with railroads.

More than ten years have elapsed since the question was first mooted of a railway to connect the Congo with the Nile.

On May 3rd, 1906, the British Government and the Sovereign of the Congo Free State entered into an agreement which provided for a railway between the Congo frontier and the latter river. The construction and working of this line were to be conceded to an Anglo-Belgian company, on terms to be agreed upon between the Sudanese and Congo Governments, and in order to secure the capital expenditure required the Egyptian Government undertook to guarantee 3 per cent. interest on a sum not exceeding £800,000.

This agreement has not so far been carried out, and possibly never will be. Besides, its practical interest is, to a large extent, subordinate to the construction of the much longer section from the Anglo-Belgian frontier to the Congo River.

A considerable traffic, passing mainly through Aba, is rapidly developing between the Sudan and the north-eastern districts of the Colony; Greek and Arab traders are bringing goods into the wholesale stores of Khartoum and taking out considerable quantities of ivory and rubber. Moreover, now that the great mineral wealth and climatic advantages of these regions have been realised, the importance of opening up this country has become more tangible.

Two almost parallel but by no means competitive lines are in contemplation. The first track would start from a point either near Bunba or near Basoko and extend *viâ* Buta through a rich palm country and the Moto goldfields to Aba. It is to be noted that access to Buta is at present afforded by the Itimbiri River, which, however, is impracticable to steamers during five months of the year.

The other line has already been surveyed. It would connect Stanleyville and Mahagi (Lake Albert) *viâ* Iruma with a branch to the Kilo and eventually to the Moto gold mines.

In the present conditions, Kilo and the surrounding country up to about 150 miles west of Lake Albert, can be more conveniently approached from Mombasa than from Boma. The Mombasa route comprises rail and water transport up to Masindi Port on Lake Chioga, motor transport to Butiaba on Lake Albert, a steamer service across the lake to Kassenye, from whence a short but very steep road leads up to Kilo. The facilities between Masindi and Kilo will no doubt be improved in the near future. But when once the contemplated connection with Stanleyville is established a keen competition will in all probability arise between the two routes. I venture to say that this prospect should by no means delay the completion of either; the development of this part of the Congo, without taking into account the local trade, will I feel certain procure abundant traffic both for the eastern and the western routes.

At the Berlin Conference, Sir Edward Malet, the British Plenipotentiary, asked Stanley if, in his opinion, the railway from Vivi (Matadi) to Stanley Pool would be sufficient as a commercial outlet for the commerce of the Congo basin, and Stanley replied "Certainly not."

The soundness of this prediction is becoming every day more manifest. It would be childish and futile to attempt, as the wish has sometimes been expressed, to direct the entire traffic of the Colony towards the main river, and the Stanley Pool and Matadi railway.

To-day the bulk of the Upper Katanga output

is carried southward and shipped from Beira. A few months hence the alternate route of Bukama-Stanleyville-Matadi will be open. A third—shorter and perhaps cheaper—channel to the ocean, the Benguella railway, will probably be available at a not far distant date. A fourth track has already been fully surveyed which, crossing the tributaries of the Kasai River at approximately their navigable termini, would connect the Katanga railway with the Lower Congo line.

Should the latter scheme mature, as we may reasonably expect it will, not only would a means of rapid communication be established between the Atlantic ports, including the capital of the Colony, and Elisabethville, but one of the best-endowed and most densely inhabited regions of the Congo would be rendered accessible to adequate development.

A branch line would probably extend to Lusambo, the head port of the Kasai River. According to another scheme, this locality would be connected by a railway *viâ* Kabolo to Lake Tanganyika.

Finally, it should be mentioned that the French contemplate tapping the resources of the Congo basin by means of a line from the Atlantic to Stanley Pool (Brazzaville), of which a finished section, from the Pool to the copper-mines of Minduli is already feeding the Lower Congo railway. The Portuguese also are pushing forward their Northern Angola railway from S. Paolo de Loanda towards the Upper Kasai.

Each of these routes will serve a distinctive purpose and none of them will be superfluous. The wealth of the Congo cannot find too many outlets.

I shall not enlarge on the controversy as to the respective merits of railways and waterways. Some day it may be found expedient to improve the less navigable river stretches, including those alongside which railroads have been laid down. It has been estimated that even the rapids of the Lower Congo can be overcome at the comparatively low cost of £4,000,000. May I be permitted to submit that the effect of parallel lines of railway and navigable water is not to diminish but rather to increase each other's utility and traffic?

The presence of fly renders animal traction impracticable in the majority of districts, and the luxuriant vegetation and heavy rainfall make the upkeep even of metalled roads an arduous task.

Yet without a good network of roads the country could only partially be opened up for administration and commerce. The winding native paths cannot suffice.

Although a very large amount of work is urgently required to be accomplished in this direction, the aggregate length of State-built roads already exceeds 5,600 miles. This figure includes a motor road on which a motor transport service is established between Buta and Bambili (154 miles), connecting the navigable Itimbiri and the Uele River.

A company working the diamond mines of Tshipaka (Southern Kasai) has constructed a motor road alongside the Wissman Falls.

The following are the principal caravan routes generally provided with porterage services and rest houses: from Niangara to Aba towards the Nile; from Kilo to Moto; from a point above Ponthierville to Lake Kivu; from Lusambo to Ankoro (above Kabalo), and to Bukama; from Lake Moero to Elisabethville and towards Ankoro.

Speedy and, above all, cheap means of transport are to the Congo a matter of paramount importance for the development of its resources, the prosperity of its inhabitants, its commercial intercourse with the adjacent colonies, and its sea-borne trade.

Although superior to probably any other country in the abundance and variety of its natural gifts, its promise is impaired by one disadvantage—distance.

In order that its output of agricultural and mineral produce may compete in the markets of the world with that of other lands less favoured in all respects except as regards distance, excessive cost of transport should not impede either the introduction of plant and machinery up to the remotest regions where dormant wealth awaits to be aroused, or the circulation and outflow of the riches yielded by its soil.

The present Government of the Colony have given ample proof of their readiness to sacrifice immediate revenue for the indirect and ultimate benefits accruing from enhanced prosperity, and I think I may confidently say that, subject to a fair and generous regard for vested rights, they would not hesitate to set aside such private interests as might be found to stand in the way of progress.

To make a brief reference to other means of communication in the Colony. There are at present fifty-one post offices dotted over the country; nearly 2,000 miles of telegraphic lines (Boma - Stanley Pool - Coquilhatville; Kabalo-

Kalenie; Kambove-Sakania), and fifteen wireless stations (Banana, Boma, Kinshasa, Coquilhatville Basankusu, Umangi-Lisala, Basoka, Stanleyville, Kindu, Kongolo, Lukuga, Kinkondje, Elisabethville, Lusambo and Kilo). It will be noticed that ten of these stations have been erected at nearly regular intervals along the curve of the main river. They form an uninterrupted chain of communication between Boma and Elisabethville.

The Congo is connected at Banana with the "Eastern" cable system. Reuter's messages are received regularly in the principal localities, and posted up within a few hours from their issue in Europe. Besides official bulletins and missionary periodicals, the press is represented in the Colony by two local papers.

As for banking facilities, the Congo possesses only one—but very active—financial institution, viz., the Banque du Congo Belge, a Government-controlled bank of issue.

As an indication of the activity of the Colony, I may mention that the amount of remittances —passing through the bank—from the Congo to the neighbouring colonies or Europe, and *vice versâ*, at present approximates £4,000,000 per annum.

In this connection, the fact that since the beginning of 1915 the Congo exchange has not exceeded the rate of 25.50 francs per one pound sterling, may perhaps be regarded as worthy of notice. In the present circumstances, the Congo finds its principal markets, both for sale and for purchase, in the United Kingdom and British Possessions. Thanks to the comparatively high value of its currency—a corollary of its favourable trade balance—the Congo has been able to obtain goods without the additional charge of a premium in respect of exchange. An inflation of prices and wages has been thereby avoided, whilst the stability of the exchange has relieved the Congo trade and its suppliers of what might have been a very disturbing risk.

Reviewing the Colony's equipment, some of the essential features of its economic legislation can hardly be passed over in silence.

In accordance with a theory embodied in the legislation of most countries, the very first Ordinance (July 1st, 1885) of Sir Francis De Winton, the first Governor of the Congo, proclaimed that all unoccupied land would be regarded as the property of the Crown.

It has been argued that there is no vacant land in the Congo; that, according to native custom, practically the whole territory is divided up into contiguous areas held in communal ownership. But this view appears to be founded on a confusion between the political and the private rights as established by native tradition. Although a right is frequently claimed by tribes, or groups of families, to prohibit a stranger to the community from establishing himself, or from hunting, within certain boundaries unless he be granted permission to do so and agree to pay a tribute, corroborative evidence from all parts of the Congo goes to prove that the natives do not consider that they are entitled to an exclusive right, either communal or individual, except in respect of the land they have cleared, the cultivations they have established, and the trees they have planted or improved.

In practice, whatever may be its legal merits, a reasonable application of the principle which has been laid down in the Congo should not differ materially from that derived from the alternative theory which would vest the original ownership of all land in the natives, but would give the Government, the trustee for the native, power to dispose of the land in the best interest of the latter.

The manner in which the Free State Administration made use of the Crown land thus defined has given rise to vehement criticism. Before the establishment of European rule, the natives of the Upper Congo had left the exportable produce of the Upper Congo, notably rubber and gum copal, practically untouched. The soil bearing such produce, not being turned to any account, constituted vacant land within the meaning of the law, and consequently fell to the Crown. For the two distinct purposes of obtaining revenue and, by the offer of a strong inducement, of overcoming the reluctance of commercial enterprise to enter the Upper Congo, the Free State Government conceded to private companies the use, within huge areas, of all domanial land, and consequently an exclusive right to the principal exportable products therein.

The natives being taxed in kind, or for the estimated amount of labour required to collect a certain amount of produce from Crown lands, the exportable supplies thus obtained were included in the receipts of the beneficiary companies.

As a result of this policy, the country was to some extent opened up and a good deal of promiscuous planting was carried out in accordance with the terms of the concessions. But lack of competition, coupled with the pressure

which was brought to bear on the native tax-payer, permitted abundant profits without effecting either an industrious improvement of the land or an adequate remuneration for the natives' exertions. The Belgian Government have cancelled this system. Subject to the rights of third parties, the natives to-day enjoy the free disposal of the natural products of all land belonging to the State.

All the concessions referred to, with the exception of three regarding which negotiations were pending at the outbreak of the war, have been rescinded. But the Government still uphold their right to dispose of State land in whatever manner they may consider best calculated to benefit the interests for which they are responsible.

The law (Decree of June 3rd, 1906) defining the native rights of occupation has been found rather obscure and unworkable, and is at present under revision.

But it is the spirit in which a legislative system is carried out, rather than the words in which it is framed, that really signifies. The soil of the domanial land, in the same way as the natural products thereof, have been placed at the free disposal of the native communities. No hindrance is laid in the way of their planting or cultivating as much land as they please, or of their disposing of their crops as they think fit. Whenever land is granted to non-natives, ample reserves are marked out for the neighbouring native villages. If a native desires to acquire a right of individual ownership with regard to a plot of land, this wish is readily acceded to, subject to no other stipulation than that, after a time, he must show a moderate amount of improvements as a condition of the maintenance of his tenure, and that he is precluded from leasing or selling the land to non-natives during a certain period, after which the lease or sale is subject to no restriction whatever. This is the only case in which a non-native can obtain possession of native land without the sanction of the Government, a provision which has been enacted with a view to protect the native communities from despoiling themselves of their reserves.

Grants of land are given to non-natives on very liberal terms. Land for agricultural purposes can be purchased at about 1*s.* 7*d.* per acre, or leased at about 1*d.* per acre per annum. The price of a plot of about 2½ acres for a factory outside a township is £40. Within the principal townships well situated allotments are, however, rapidly appreciating in value.

The transfer of land is subject to a uniform tax of £1 only.

The grantee is required to carry out a certain amount of building, planting, cultivation, or other development. In more important cases he is liable to be called upon to prove that he disposes of a sufficiency of initial capital to enable him, with a reasonable prospect of success, to undertake the working of the land he applies for, and a minimum wage and eight-hour day are stipulated in favour of labour in his employ.

In short, the policy of the Government is to apportion the soil of the Colony in the manner in which it may be best turned to account, reserving first to the natives such land as they are utilising or may, in a not too far distant future, hope to develop, and offering the remainder to European enterprise.

The law of the Congo, as in most, if not all, Continental legislation, attributes to the Crown the ownership of the sub-soil, whoever be the owner of the surface.

In the Katanga Province, a two-year prospecting licence can be obtained for £4. The working of minerals discovered is subject to a royalty of 1 per cent. of the value of the output, except in the case of precious metals and diamonds, in which case it is 5 per cent. ; and 33 per cent. of the net profits go to the Treasury.

In all probability this system will be extended to the other provinces. A previous administration gave one large company exclusive prospecting rights over the greater part of the Colony outside Katanga. These rights, of which diligent and successful use has been made, have already partially lapsed, and will expire in the course of the coming year.

The goldfields of Kilo and Moto, which have been mentioned several times, are at present worked by the State. A good deal might perhaps be said in favour of breaking up this area into private "claims." But, whilst the country is hardly ripe to receive a gold rush, the output in these mines affords an opportune item of revenue, and their working entails no competition with private enterprise. All things considered, I believe that the present method of developing this valuable asset is, in the general interest of the Colony, the most appropriate for the time being.

As stipulated in the Berlin Act, the Congo is a country of absolute free trade.

There is no differential treatment in favour or to the disadvantage of any nation or individual with regard to either shipping facilities

or the export and import of goods, nor is there any monopoly in commercial matters.

Hawking is subject to the payment of an annual tax of £8 to £20; but neither a householder nor a native requires a licence to trade.

Except in respect of spirits, import duties are limited to 10 per cent. ad valorem. Seeds and fertilisers enter free; industrial and agricultural plant and machinery pay 3 per cent.

The 10 per cent. limit to which the Congo is restricted by an agreement entered into at the Brussels Conference (1890) may be considered unreasonably low for luxuries such as, for instance, high-class tobacco.

Ivory, gum copal, and rubber are liable to an export duty. The last-named produce is, however, not dutiable when the market price in Europe stands below 1*s.* 10*d.* per lb. for vine rubber, or 1*s.* 1*d.* per lb. for grass rubber. Plantation rubber goes out free. Export duties placed on other produce by the Free State Government have been repealed.

Direct taxation is established on a very moderate scale. There is, as yet, no income tax.

As to the natives' contribution towards the cost of administering the Colony, the former system of taxation in kind and assessment per tribe or village has been entirely abandoned. Besides the risk of an arbitrary estimation of the produce tendered in payment, it exposed the weaker members of the native communities to unfair pressure on the part of their chiefs.

The Government is authorised to impose an annual tax of 1*s.* 7*d.* to £1 per adult male according to the economic situation of the various districts. In practice, the maximum rate has been 9*s.* 6*d.*, the minimum 2*s.* 4*d.* Females are not assessed, but the male taxpayer is liable to an additional tax of 1*s.* 7*d.* to 4*s.* 9*d.* for every wife but one, with a limit in certain regions of £10 to whatever number he may have carried his matrimonial acquisitiveness.

For the financial year 1916 the yield of these native taxes amounted to a little over £400,000. A small figure with regard to the multitude of possible tax-payers, but a large one if we consider that this taxation is very leniently applied, and that the use of coin has only been disseminated in the Upper Congo within the last few years.

It may be worth mentioning in this connection that, in order that the natives shall be better protected against unfair dealings by a more definite knowledge of the relative value of the commodities purchased or sold, a law prohibiting barter between the native and non-native has recently been enacted.

The educational value of a moderate tax in cash is indisputable; in remote districts it frequently constitutes the initial inducement for the native to approach the trader or employer of labour with an offer of produce or service, and having devoted part of his first earnings to the purchase of European commodities the native acquires new needs and more industrious habits.

To conclude this long enumeration, I must refer to the part taken by private enterprise in the building up of the present plan of the Colony.

The aggregate capital of Congo Joint Stock Corporations approximates £29,000,000 sterling, and there are about a thousand factories of which, of course, a large proportion are owned, not by companies, but by individual traders.

But the capital which private enterprise has invested in improvements constitutes, I should say, a smaller asset than the ability and energy of the men who "at home" or "out there" are devoting their exertions to the development of the Colony. The best guarantee for its growing prosperity and participation in the commerce of the world which the Congo possesses lies in the steadily increasing number of its factories, settlers and hawkers, and of business men, who take an interest in its ventures, and of manufacturers and merchants who are studying and endeavouring to supply its special requirements.

If I may venture to single out two names typical of the co-operation of Belgian and other capital in the Congo, I should mention M. Gean Jadot, the far-sighted and vigorous Governor of the Société Générale de Belgique, the moving spirit of several of the principal and most valuable enterprises in the Colony, to whom notably is very largely due the extraordinarily rapid progress of Upper Katanga; and Sir William Lever, who is undertaking the development on scientific lines of some of the oil-palm forests forming part of the dormant resources of the Congo, and who by his methods and by his achievements is establishing a precedent no less beneficial to the Congo native than are, for the European working-classes, the great examples which he has set at Port Sunlight and elsewhere.

This—necessarily very incomplete—description of the present organisation and plant of the Congo will have failed to give a fair impression

of the actual position if it has not clearly manifested two facts—namely, that considerable endeavours have been made to open up and to bring the natural gifts of the country into bearing, and that nearly the whole of this work has been either initiated or completed within the last eight years. We must further bear in mind that, during more than one-third of this short period, the commercial and administrative development of the Colony has to some extent been hampered by the abnormal conditions arising from the great struggle in Europe, and by the campaigns into which the Congo has itself been obliged to enter.

In the light of these considerations, the following returns should be regarded as being merely the first fruits of the present equipment. The figures given are those most recently available. The £ sterling is taken as an equivalent of 25.25 francs.

The exports (special trade) for the year 1915 were valued at £2,850,000, this being the highest figure of an almost continuous progression, viz. :—

	£
1887	325,000
1890	433,000
1895	1,426,000
1905	2,098,000
1910	2,638,300

Any comparison of these amounts must take into account the exceptionally high price of ivory in 1905, and of rubber in 1910.

Quantities, however, afford a more definite indication than values. Here are some items out of a list of over 150 :—

	1913 (last pre-war year).	1916 (first half-year only).
Rubber	7,998,000 lb.	2,311,300 lb.
Ivory	5,524 cwts.	2,727 cwts.
Gum copal	4,697 M. tons.	4,080 M. tons.
Palm kernels	7,205 "	9,280 "
Palm oil	1,974 "	1,588 "
Rice	3½ "	582½ "

As regards minerals, the following tables give the output of the principal mining centres :—

Year.	Copper (Katanga). M. tons.	Diamonds (Kasai). Carats.	Gold (Kilo and Moto). Ozs.
1913	7,400	15,000	43,600
1914	10,700	39,000	55,000 (approximate)
1915	14,200	50,000	82,800
1916	22,200	60,000 (approximate)	95,200

The gratifying progress which these figures indicate only foreshadows the magnitude of the future.

In Upper Katanga, the Union Minière, a Belgian enterprise of which a British company holds about 40 per cent. of the capital, is diligently extending and improving its powerful installations; and the annual output of this undertaking alone is expected to amount to 50,000 tons of copper by 1920, and 100,000 by 1925.

The first shipments of tin are on their way to Europe.

The working of the Kasai diamond deposits has only just started, and the opening of other areas has been postponed until after the war.

This also holds true for the ascertained goldfields in various districts, and for the coal mines of Northern Katanga.

Amongst the European plantations, the Mayumbe cocoa firms were practically the only agricultural venture which had been successfully attempted before 1908. They are affording an increasing yield of excellent produce.

The experimental station at Barumbu (Aruwimi district) has demonstrated that there are as good or better possibilities for cocoa in the Upper Congo, and in the future this cultivation lies doubtless mainly in the central districts of the Colony.

Sugar, coffee, tea, tobacco, sisal-hemp, pineapples, bananas—to mention but a few examples—are bound to retain the attention of the European planter. It is from the Congo that the "coffea robusta" was introduced into the Dutch Indies, where it is used to the exclusion of almost every other variety. Sugar-cane is grown in the equatorial regions in every native village, and the local consumption would, I believe, suffice in itself to warrant systematic planting and the establishment of a sugar factory. The coconut will flourish as far inland as Stanleyville.

Congo rubber—vine and grass—the standard of which is being maintained by means of Government inspection, still holds its own against plantation rubber, and in view of its specific qualities will in all probability continue to do so. There is, however, no reason why plantations should not, with the same success as in any other part of the world, be carried on concurrently with the working of the wild product. Experts generally agree that Hevea (Para) would for this purpose be preferable to the indigenous Funtumia (Ireh).

The forest wealth remains almost untouched.

An enormous quantity of timber and pulp will some day be drawn from these inexhaustible reserves.

The manufacture of methylic alcohol is already arousing interest, and the more precious varieties of wood—which are admirably suited for panelling and veneering, neglected so far except for local use and a few occasional shipments—will probably commence to be worked in the immediate future.

The systematic extraction and export of piassava, raphia, and other fibres, of which there is an unlimited supply, should prove a most attractive proposition.

As yet, however, the fruit of the oil-palm is the only forest product, other than rubber, which, to any appreciable extent, has been exploited.

The Huileries de Congo Belge, an associated company of Lever Bros., Ltd., founded in 1911 with a capital of £1,200,000, is applying the spirit of organisation, which the African native lacks, to the clearing and improvement of extensive palm areas in the Bangala, Aruwimi and Kwango districts. Four mills, with an aggregate capacity of over 30,000 tons of fruit per annum, are already working, and others are under construction. This bold enterprise, of which the success is already manifest, cannot fail to call forth similar ventures in other regions, where huge tracts of palm foreets are still lying waste.

However, in many parts of the Colony the natives have, in a desultory manner, from time immemorial been gathering palm fruit and palm wine, from the abundance of trees disseminated by Nature; and in a number of instances they have established a small plantation close to their village. But, except in the Mayumbe, only a trifling fraction of the palm wealth of the country commensurate to the local consumption has been thus turned to account.

The gigantic oil and kernel production of the British West African Possessions conclusively shows what can be produced by the unaided efforts of the natives. Yet I should say that, where sufficient fruit is available to feed a mill, it will be found to the general interest that the wasteful and toilsome native methods should be superseded by the methods of European industry.

On the other hand, the working of small palm groves, of which there are a multitude in the Congo, may best be undertaken by the native as a farm industry; and now that exceptionally high prices have stimulated the trade in the Upper Congo, we shall certainly, and in a very short time, see an enormous progression in the native output.

It may be disputed whether the native can compete with the European for certain cultivations, such as cocoa. For others there can be no doubt that native farming will stand unrivalled. This, I believe, will be the case with the majority of low-priced produce wherever labour is abundant and is not engaged on more remunerative work.

Notwithstanding the natural facilities which the country affords, a very large part of the population is underfed. The increased production and better distribution of certain foodstuffs must be regarded as one of the most important improvements brought about in the last few years; nevertheless, much remains to be done in this direction.

To give an illustration. Until quite recently rice was being imported at great expense, and consequently in small quantities, into the Upper Congo. In 1916 the region of Stanleyville alone produced over 5,000 tons, and it is estimated that by 1918 the total rice crop will—after allowing for local requirements—leave an exportable surplus of over 15,000 tons.

A similar future awaits cassava, maize, ground-nuts, sesame, castor and other oil seeds.

Although conclusive experiments have only been made in the course of the last few years, I am convinced that cotton will soon become a staple of the Congo. In the Maniema district the test may be regarded as decisive: not only has the grade obtained been highly satisfactory, but the natives have shown remarkable eagerness in adopting the new cultivation. Henceforth, during the harvest season, weekly markets will be established, the State guaranteeing a minimum price. This system is being extended to other regions and to other produce.

The Colony is only just beginning to reap what the authorities and private initiative have sown. Whilst I fully realise that disappointments and setbacks are inherent in every human enterprise, I am confident that the Congo is now steadily going ahead, and with surprising speed, towards an undreamt-of prosperity. An authoritative estimate made shortly before the war, calculated the probable value of exports for the year 1924 at £10,000,000. I am inclined to believe that the actual figure will be nearly double that amount.

A corresponding increase in imports may be expected. Imports (special trade) had reached £2,805,000 in 1913, as compared with £824,000

in 1903 and £363,000 in 1893. This figure, to the extent of about 35 per cent., included plant and machinery. Ten years hence the consumption of imported goods by the natives alone, should, at the low average rate of 10s. per head, total over £7,000,000 per annum. In addition, there will be the upkeep and extension of public works to provide for, as well as an enhanced demand for commodities and technical appliances proportionate to the growing number of white settlers and traders.

So much for the prospective progress of the Colony within the next few years.

Looking further ahead, I hardly dare say what I picture to myself the country will be like, say, half a century hence when the Congo, the Heart of Africa, with a black population of 30,000,000 or more, and a white population of several millions, will—through many arteries, north, south, east and west—be pouring out gigantic supplies of raw material, and throbbing with the activities of some of the greatest industrial centres of the world.

The realisation of these prospects presupposes a sufficiency of two essentials—men and money.

Will enough capital be obtainable to open up the country further, extend its trade, develop its resources, increase the well-being of its inhabitants?

Will an adequate number of efficient men devote their energies to its administration and to its commerce?

There can only be one reply—the necessary money will be found, the right men will come forward.

The war has depleted the stocks of raw material in Europe, and it has popularised the use of certain manufactures, such as margarine, and thereby permanently increased the consumption of various products.

At no previous time were the potential supplies of the Congo more likely to attract attention or to stimulate commercial enterprise.

On the other hand, a considerable portion of the costly and powerful machinery which has been laid down for the production of munitions of war will be adapted and employed for industrial purposes. Moreover, territorial changes, fiscal measures, and reasons of sentiment will direct the trade of the now belligerent nations towards new channels. Can we assume that the Allies will omit to avail themselves of the openings afforded by the Congo?

In view of these circumstances, I am inclined to think that, after the conclusion of peace, plant and machinery will be procurable for public works on exceptionally favourable terms both as regards price and payment. Nor do I anticipate that the financing of remunerative undertakings will encounter any considerable difficulties.

As to administrative requirements, the more recent Congo Budgets have shown an excess of expenditure over revenue, which has caused some writers in England—and I regret to say, certain Belgians—to voice a doubt, loudly echoed in Germany, as to the ability of Belgium to bear the cost of governing her Colony.

Now, it is a fact that, since Belgium took over the Congo, annual expenditure has been materially in excess of revenue; but a closer examination of this deficit, put down at £640,000 in the estimates for 1917, will be found to be largely due to what may be called establishment expenses, and must be regarded as the inevitable consequences of the Government's determination to occupy, study, and organise the country with all possible celerity.

The soundness of this policy from a financial point of view, irrespective of all other considerations, is already proved by a considerable increase in the returns. During the next two or three years the work in hand will be completed. Provision has been made for the necessary means. After that, the fiscal yield on the outlay involved will, I am confident, suffice to ensure the maintenance and progress of the Colony. Obviously loans will have to be issued to cover the expenditure on railways and other public works. But besides the security which they may afford, the investor will find a safe guarantee in the general wealth of the country and in the character of its administration. I think the Belgian Government has fully proved the value of its bond; and, as the late Mr. J. P. Morgan said shortly before his death, "Character is more than collateral."

Before the war (returns of 1912) Belgium participated in the aggregate exports and imports of the Congo to the extent of about 80 per cent.; the British Empire for about 8 per cent. In the present conditions, when Belgium lies fettered, I should say that the Empire's share amounts to at least 75 per cent. A large proportion of this trade is, however, being carried on by Belgian firms, who are temporarily enjoying the hospitality which the Government and people of this country have so generously extended to my compatriots.

Liberated Belgium will find in her Colony an

invaluable source of supply to replenish her exhausted warehouses and revive her commerce, as well as a sure customer to refill her order book. She can continue to rely upon her leading banks, who have taken such a prominent part in the development of the Congo.

But commercial enterprise and the capital of all friendly nations will find an ample and remunerative field and outlet in the Belgian possession. Need I add that such co-operation will be most heartily welcomed?

Will Belgium find the right men to administer her Colony?

She is the youngest among colonising nations, and it takes time to form a class of experienced officials. Yet a number of her sons have long since gained repute in the Far East, in Persia, in South America; and the annals of the Congo already comprise a long list of names whose bearers have displayed the persistency and valour which recent events have shown to be inherent in their race.

With all due respect to the eminent representatives of the Crown in other Colonies, I venture to say that it will be difficult to find a more capable, active, and high-minded Administrator than the present Governor-General of the Congo, Monsieur Henry.

The average standard of men offering their services to the administration and commercial concerns of the Colony is incomparably higher than it was only a few years ago; and there is good reason to believe that many will be eager to go out who, but for the war, would have held back, notably amongst those who have become accustomed to the venturesome open-air life of the trenches or have learnt the fascination of Africa in the Congo campaigns; but also amongst those whose tragic memories or the ruin of their homes in Belgium will urge to seek a fresh career and livelihood in the new territories of their mother country.

When King Albert ascended the throne, seven years ago, he proclaimed his resolve to endow the Belgian Congo with a liberal and beneficent administration. Inspired by his example, and encouraged by his support, Monsieur Renkin, the first Minister of the Colonies of Belgium, has, up to this day, unfalteringly pursued—as he will, I hope, continue to do for many years to come—the fulfilment of this comprehensive programme. Belgium is proud to be entrusted with the development of the Congo, and she will joyfully further the efforts of whosoever may be willing to assist in the accomplishment of this great duty.

DISCUSSION.

The Chairman (Mr. Steel-Maitland, M.P.), in opening the discussion, said he thought the paper illustrated one or two points which had been more and more clearly revealed in recent years, and particularly by the course of the war. When the author exhibited on the screen the map showing the various means of communication throughout the Belgian Congo, in the heart of equatorial Africa, it flashed across his memory that only a few short years ago the whole of the map of the interior of Africa was a comparative blank. It was perhaps the most striking instance in existence of the way in which the whole life of the world, during recent years, had been affected by the fact that there were now no territories unappropriated and unenriched by human enterprise and industry. The last quarter of a century had seen the whole world parcelled out, so that what was done in one place, however remote, must quite inevitably have its reactions on the whole of civilisation. Another point of great interest, which up till quite recently had not been sufficiently realised, was the extraordinary fertility and powers of reproduction of natural products in the equatorial regions of the earth. Owing to the war, attention had been devoted in a way that had never been the case before, not only to rubber, but also to oils and fats. He had had very considerable reason to become intimately acquainted, not only with palm nuts from Nigeria and the trade in similar products, but the whole question of oils and fats. Before the war it was hardly realised that they formed such an important and indeed essential feature of trade and of our existence. Appreciation of the potential productivity of all the equatorial regions where there was a proper rainfall and a suitable climate for production, had come at the moment when the efficiency of white production and of machinery was increasing at a pace far exceeding anything that had happened before. The mechanical development of the nineteenth century had shown increasing powers of production, but throughout the last ten years the powers of machinery to utilise and convert natural products had progressed at an accelerated speed. All modern European countries, particularly England, had learned during the war that the capacity for production was previously much lower than it ought to have been per head of the population. If, after the war, the most was to be made of the possibilities of this country; if the standard of wages was to be sustained at anything like the figure it had reached during the war; and if, as all far-sighted men wished, the war with all its horrors should be succeeded in this country by industrial peace and not by industrial quarrels, there must be a vastly increased production in the country; and that would be brought about through the greater power of machinery, and a greater appreciation of the big tropical regions

of the earth as supplying the raw material which that machinery must use. There was an extraordinary necessity, from the point of view of human needs, for the development of the latent possibilities of those equatorial regions. He could not help expressing his own satisfaction that an ample proportion of the world's supply lay so largely in the hands of our brave Allies as well as of ourselves; and he was quite sure that all present extended their heartiest good wishes to Belgium in her task after the war—when she herself had been amply and fully rehabilitated—of further developing her great possessions in Central Africa. He trusted that work would be carried forward successfully by all the Allied nations. Since the British occupation of Togoland, a little more than two years ago, the area cultivated by the natives had increased by 30 per cent. under British rule as compared with German rule. The author had alluded to a question which must be at the back of the mind of every one who was in a position of responsibility with regard to tropical possessions, namely, the position and welfare of the native races over whom this country had a Protectorate. As M. Horn had said, the natives were entitled to a portion of the goods of the country which they produced, and Belgium and this country looked upon themselves as being primarily trustees for the benefit of the native races who lived in the Protectorates. From that point of view it was necessary, in the development of the country, to consider not only their tribal customs, but also their own civilisations, differing as they did from the most rudimentary to some that, as in Northern Nigeria, were quite far advanced. It was also necessary to consider respect for their own persons, so that what was by many thought to be an advance of civilisation for them, was really and truly a blessing in fact as well as in name. If that was their duty as trustees, he thought that after the war the problem that would have to be solved in this country was to harmonise our primary duty as trustees for the natives with a full development of the country for supplying the wants of modern needs in the more temperate regions. He suggested that the audience should carry away from the meeting, first of all an appreciation of the paper; secondly, an idea of the extraordinary fertility of the possessions in Central Africa; thirdly, the need that these possessions should be developed; and, fourthly, the great duty that lay upon them of harmonising that need with their primary duty as trustees toward the native races that lived in those parts.

M. RENKIN (Ministre des Colonies de Belgique) dit: Les vues exposées par M. Horn sont exactes. Le Congo est une colonie magnifique et le désir non dissimulé d'une puissance pour qui la force prime le droit de s'approprier la Colonie Belge est une preuve irrécusable de sa grande valeur. Je crois pouvoir affirmer aujourd'hui qu'autant et plus qu'avant la guerre, les Belges ont à cœur de conserver le Congo et de travailler à son développement futur. Je dis plus qu'avant la guerre parce que l'Union s'est faite aujourd'hui entre tous les Belges sur la question coloniale. Tous entendent conserver la Colonie. Les sentiments de sympathie exprimés à l'occasion de cette réunion causeront à tous les Belges la meilleure impression. L'occupation de leur territoire par l'ennemi a privé les Belges de toute leur activité intérieure. C'est dans la Colonie qu'ont pu s'affirmer l'énergie et la vitalité de la nation Belge dans le domaine de la guerre aussi bien que dans celui de la paix. Les chemins de fer ont été développés pendant la guerre, les exportations sont cinq fois plus importantes, ce mouvement ne fera que s'accentuer. La Belgique comprend qu'elle peut, grâce en partie à sa Colonie, prendre une large part dans le développement et la reconstruction de l'industrie en Europe, grâce à l'extension des cultures et à l'exploitation des matières premières que le Congo contient en abondance. Les nations colonisatrices ont un but supérieur qui est de protéger et d'élever les indigènes et, dans ce domaine également, la Belgique ne faillira pas à son devoir. Ce qu'elle envisage surtout en matière coloniale c'est l'extension de la civilisation. C'est pour la justice et la civilisation que la Belgique s'est sacrifiée au début de la guerre et c'est pour cela qu'elle continuera l'œuvre dont elle a accepté la responsabilité en Afrique.

SIR WILLIAM H. LEVER, Bt., said that, as one who had travelled with M. Horn through the Belgian Congo, he was of opinion that the author had not overstated the prospects of the country or the great work that the Belgian Government carried on there; in fact, he had understated and underestimated whenever he had ventured either to make a statement or a prophecy. Personally he wished the author had drawn the picture a little nearer those sanguine lines which he was sure in his heart of hearts he thought was correct. The Congo was offered by Stanley in succession to the United States, England, France, and Germany—but they all refused it. Belgium possessed a far-seeing King, who saw the immense possibilities of the country; he took an early train to Marseilles, met Stanley on his arrival there, and secured for his country what had been refused by the great nations of the world. It was right, therefore, that Belgium should enjoy the benefit of the foresight of its King. Whatever had been heard about the cruelties to the native races in the Belgian Congo had a German origin, and were substantially not correct. The cruelties imposed on the natives were part of the native chiefs'

form of government. There was no gaol and no imprisonment as in this country, and the punishment for theft and every other crime was mutilation; and the natives mutilated by the native chiefs formed the basis of the stock, panicky cry in England against the Belgian Government. At the same time he did not mean to say that no cruelties had been perpetrated on the Congo natives, and it could not be said either that cruelties had not been perpetrated on the natives in British Colonies, but they were grossly exaggerated, and were not correct as told to the public of this country. With regard to the attitude taken by this country to native races, whenever he went into English Colonies he always found an outcry against what was called "Exeter Hall." It was a curious fact that in the House of Commons the same people stamped, and stormed, and raved about the iniquity of dukes, who held their land for their own comfort and kudos and not for the service of their fellow men, and it was considered wise that statutes should be enacted to compel dukes to use their broad acres for the general benefit of the public. But the same men said in regard to a black man, who might or might not be a prince, that this country had no right to interfere with his land, and that he must use it or not use it as he liked; that there might be countless millions in Europe starving for oils and fats and for all the produce that generous Nature could pour forth under tropical suns and tropical showers, but the black man must not be interfered with. He did not consider that that was good government. There were good black men and bad black men, and good white men and bad white men; but he did not see why we should have a sentiment for a man because of his colour. Nevertheless, that was the case in British Colonies all over the world. In his opinion the world was meant for the use of the people who were at present living in it, and the man who could make use of the tools, whether the hammer, the chisel, or the broad acres, for the benefit of the general public had a right to them. The only title of every white man or black man was to make the best use of them for the public. He believed the black man could be spoiled as much by sentiment as by brutality, and he understood the latter better than the former. But neither of them need enter into the question of the government of the black man. The main thing was the education of the native, and the Belgian Government were showing the English the way in that respect. If the black boy was educated from an early age, great use could be made of him. It was absolutely necessary to remember that the country would never be developed unless the black men who lived in it were educated. White men were not necessary there. The black man could get on without the white man, as he always had done, but the black man was necessary to the white man. It was impossible for progress to be made in the tropics without the aid of the black man. If the black man disappeared, as he had in some parts, the whole place would become a desert. Having educated him, the next subject that must be dealt with was transportation, and that was being dealt with by the Belgian Government through the building of railways and the making of the rivers navigable. Boats must be put on the rivers, and produce carried for the smallest traders at equal rates obtained by the largest, so that all were placed on one level of equality in competition. That policy, in his opinion, would do more for the black man than sentiment. He must be educated, trained, and disciplined; but, above all, it was necessary to be firm with him and let him understand that the land that he might call his own or not had to be developed and exploited and made to produce the fruits of the soil. On those lines, which the Belgian Government were following with great ability, the tropics would yield their full and abundant harvest for the benefit of the white man in the temperate countries.

MAJOR E. H. M. LEGGETT, R.E., D.S.O., in moving a hearty vote of thanks to M. Horn for his paper, said the author had given a compendious account of the problem connected with the place which Africa held, and would hold in the future, in the economic life of the world. It might not be known to the majority present that when His Majesty King Albert visited the Belgian Congo as Prince Albert, to inquire into the supposed atrocities, which it was now known were persistently exaggerated and even invented by the Germans, he was accompanied by M. Renkin; and it was at that time that the lines of government and development described in the paper were laid down. They had been followed ever since, and had resulted in a marvellous development which was the subject of the respectful admiration of the people of this country. It was a blessing for the world that so large a part of Africa was in the hands of our enlightened friends and Allies the Belgians. Many people had not realised that perhaps of all the continents of the world Africa stood to gain most from the war, namely, that for all time the native races would be free from the play and counterplay of opposite schools of thought, action and government. Belgium, France and Great Britain were working on the lines of recognising, first of all, the trusteeship of the white for the black; secondly, the education of the native stage by stage, through the lines to which he was accustomed up to the higher forms of agriculture and mechanical and industrial development; and the German system of government, which was so diametrically opposite, had been eliminated from African soil. It was, therefore, not too much to say that millions of Africans yet unborn

would benefit from the present terrible war, to an extent that no other country outside of Europe could.

THE HON. RICHARD CLERE PARSONS, in seconding the motion, said the only security that the Belgian Congo could have against invasion, in the way its Mother Country had been invaded, was that the British Fleet should continue to occupy the seas of the world. He hoped the British Fleet would for ever rule the seas, so that peace throughout the world might be ensured.

The resolution of thanks having been carried unanimously, M. Horn briefly acknowledged the compliment; and Sir Frederic W. R. Fryer, K.C.S.I., having expressed the thanks of the Colonial Section Committee to Mr. Steel-Maitland for his kindness in taking the chair, the meeting terminated.

OBITUARY.

REGINALD LE NEVE FOSTER.—Mr. Reginald Le Neve Foster died at Torquay on February 11th. He was the fifth son of Peter Le Neve Foster, who was Secretary of the Society from 1853 till his death in 1879. The family has been connected with the Society almost from its foundation. Peter Le Neve Foster's father—also Peter Le Neve—joined the Society in 1807. His grandfather, Abraham Osorio, had become a member in 1800, and Abraham's father, Jacob Osorio, was also a member from 1766. Jacob's brother Abraham carries the record a little further back, because he joined the Society in 1761 —seven years after its foundation. Reginald Le Neve Foster became a member in 1880, and the family is still represented by his son Basil and by another grandson of Peter Le Neve Foster, Vivian, the son of Sir Clement Le Neve Foster.

He was born at Camberwell in 1846, and was educated at London, Brussels, Stuttgart, and Prague. For a short time he was associated with Price's Patent Candle Company, and afterwards he became a pupil of Dr. F. Crace Calvert. Eventually he joined Dr. Calvert, who was the first to manufacture pure carbolic acid in this country, and to apply it to disinfectant and therapeutic purposes. In 1857 Dr. Calvert established works in Manchester for the manufacture of carbolic acid, and these were considerably developed in 1865. Mr. Foster became connected with these works, and before his death he had completed fifty years' service as their manager.

He always took a very great interest in the affairs of the Society, and in July, 1914, he presented to the Society a sum of £100 for the purpose of founding a prize in commemoration of his father. The amount was afterwards increased by a further donation to £140, and the prize was first offered in 1915 for an essay on "Zinc, its Production and Industrial Applications." The offer produced a number of valuable essays, and the one to which the prize was awarded, by Mr. J. C. Moulden, was read as a paper before the Society in May, 1916.

GENERAL NOTES.

RUSSIAN EXHIBITION.—With reference to the note in the *Journal* of March 30th, it should be added that the Hon. Organiser of the Russian Exhibition, to be held at the Grafton Galleries in May next, is Lady Muriel Paget, and that all communications respecting the Exhibition should be addressed to 32, Victoria Street, S.W. (1)

COTTON IN UGANDA.—The area under cotton in Uganda in 1915–16 was 92,217 acres, as against 118,778 acres (the record figure) in the previous year. The decrease was due to the difficulty experienced in selling cotton for over six months in the period 1914–15, which tended to discourage growers and retarded seed distribution. Practically the whole crop, which is of a high standard American grade when marketed in clean condition, is ginned in the Protectorate. The bulk of it is sent to Great Britain, but a new market has been found in India, which bought over 9,000 cwt. in 1915–16. The erection of ginning factories in centres of production, according to the Report on the Trade, etc., of Uganda, recently issued by the Colonial Office (Annual Series, No. 914), is being continued. Exports of cotton seed amounted to 5,225 tons in 1915–16, as compared with 9,017 tons in 1914–15. The seed is also used as fuel for generating power in many of the ginning factories, and as it is a bulky and low-priced commodity, the quantity exported depends largely on the shipping charges.

FOREIGN TRADE OF JAPAN.—The great expansion of the foreign commerce of Japan during the period of the war is emphasised by the official returns now available for December and for the whole of last year. For 1916 the total value of imports was 756½ million yen, being an increase of 224 millions, while the exports for the same period amounted to 1,127½ million yen, being an increase of about 419 million yen. The actual excess of exports over imports for the year was 371 million yen as compared with 176 million yen for 1915, while the changed position which has taken place since the commencement of the war may be gathered from the fact that for the year 1914 there was actually an excess in the value of imports over exports of about 4½ million yen. Instead, therefore, of having an adverse balance against her as in the pre-war days, Japan has a large surplus balance the other way.

NOTICE.

NEXT WEEK.

WEDNESDAY, APRIL 18th, at 4.30 p.m. (Ordinary Meeting.) HORACE M. THORNTON, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance." SIR GEORGE THOMAS BEILBY, LL.D., F.R.S., Chairman of the Fuel Research Board, will preside.

THURSDAY, APRIL 19th, at 4.30 p.m. (Indian Section.) R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products." Owing to the absence of the author in India, the paper will be read by LAURENCE MERCER, C.I.E., late President, Imperial Forest Research Institute and College, Dehra Dun. SIR ROBERT W. CARLYLE, K.C.S.I., C.I.E., Member of the Viceroy's Council, 1910-15, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Tuesday, March 27th, 1917; The RIGHT HON. AUSTEN CHAMBERLAIN, M.P. (Secretary of State for India), in the chair.

THE CHAIRMAN, in opening the meeting, said that they were met in a good cause, and for excellent reasons, one or two of which he would venture to mention because they would be sufficient to justify his presence in the chair. In the first place the paper dealt with an Indian subject—one of vast consequence to India but also of great interest to the scientific world of this country. It contained something of the work which was being done in the field of medical research in India, and of the great opportunities for study and for progress which were open to those who would make that field their own But he had more personal reasons for attending. The paper was written by Sir Pardey Lukis, the Director-General of the Indian Medical Service. The Civil Medical Services of India had given of their best and given freely for service in the present war. Sir Pardey Lukis, for a short time in the interval between the resignation of one Director of the Army Medical Services and the arrival from Europe of his successor, held that post; and he was glad to have the opportunity, especially in view of all the criticism—some of it just and much of it unjust—which had fallen upon Indian medical administration, of publicly paying a tribute to the admirable work which was done by Sir Pardey Lukis in the few months during which he filled that position. The energy which he threw into it and the progress which he obtained were alike remarkable, and reflected the greatest credit upon him and upon the Service of which he was so distinguished a member. The last reason he had for attending was a personal one. The paper was written by Sir Pardey Lukis, but it would be read by Sir Havelock Charles, the President of the Medical Board at the India Office, and the Medical Adviser of the Secretary of State. He was indebted to Sir Havelock Charles for all the work he had done for him at the India Office. His task was often a difficult and a disagreeable one, but he discharged it with great impartiality and great ability; and he (the Chairman) was glad to be present to pay a personal tribute to him also.

The paper read was—

OPPORTUNITIES FOR ORIGINAL RESEARCH IN MEDICINE IN INDIA.

By SURGEON-GENERAL SIR C. PARDEY LUKIS, K.C.S.I., K.H.S., M.D., F.R.C.S.,

Director-General, Indian Medical Service, and President, Scientific Advisory Board, Indian Research Fund Association.

As members of an Empire so widely distributed as is ours over the four quarters of the globe, few of my audience are likely to be unconscious of the debt the Empire owes to

medical research; nevertheless, I am justified perhaps in assuming that many of you have no clear idea of the magnitude of that debt.

It is not my purpose to direct your attention to the striking advance made by medicine and surgery during the past twenty years in the civilised countries of the West; rather I would have you look farther afield to those vast British tropical and sub-tropical dominions beyond the seas and to the smaller outposts of the Empire—countries in which England has been called on to secure the welfare of hundreds of millions of fellow subjects, 90 per cent. of whom have only a rudimentary knowledge of sanitation and preventive medicine—countries which have death-rates unparalleled in more fortunately placed Britain, and where the inhabitants are decimated by diseases—largely of a preventable nature—from which Britain is happily free.

To such British possessions I would direct your attention for a moment, and ask you to consider with me what medical research has done there in the past, what it is doing now, and what it hopes to do in the future. More especially would I direct your attention to our great Indian Empire, which is that portion of our dominions about which I am best able to speak from personal experience. Has Britain risen to the occasion and been faithful to her great trust? It is no exaggeration to say that, practically speaking, the science of "tropical medicine" has been created within the last twenty years. I have no wish to decry the epoch-making discoveries made anterior to this period, such as Laveran's discovery of the malaria parasite in 1880; Koch's discovery of the cholera vibrio, both in Egypt and in India, in 1884–1885; Vandyk Carter's work in Bombay on the spirillum of relapsing fevers; Manson's observations in connection with filaria and mosquitoes in 1879–1883; and Kitasato's discovery of the plague bacillus in 1894. With the exception, however, of those mentioned above, workers in this huge and fascinating field were few and far between. In spite of the efforts of this band of pioneers, it was not until the close of the last century that the real importance of the subject began to be realised. In this connection, the efforts of Sir Patrick Manson to obtain for tropical medicine its due meed of recognition can hardly be rated too high. In 1898 Ronald Ross, then a member of the Indian Medical Service, working on lines that had been hypothecated by Manson, succeeded in demonstrating the life-history of the proteosoma parasite of birds, showing that a species of mosquito was instrumental in conveying from bird to bird the malaria-like proteosoma parasite, for which the mosquito acted as a host. Subsequently he observed an identically similar cycle in the development of the malaria parasite itself. The importance of these discoveries cannot be overestimated. New and important fields in research were opened up, to which were attracted numerous enthusiastic workers. About this time the country was flooded by the wave of Imperialism that the late Mr. Joseph Chamberlain did so much to foster. That great statesman was the first to recognise the importance of Britain's Overseas dominions, and to impress upon stay-at-home Britons the necessity for making healthy and contented the dwellers in these vast possessions. In this way research in tropical medicine received an impetus the effects of which are seen to this day. Tropical medicine had come into its own, and two schools of tropical medicine were established in England—one at Greenwich and the other at Liverpool.

[At this point Sir Havelock Charles said: Here, in the name of workers in tropical medicine, I desire to thank our Chairman for coming to-day. We all know the immense burthen of work on his shoulders. Yet, in spite of it all, in keeping with the spirit of his father's memory, he, to show his sympathy with those engaged on work for India and the Indians, makes time to preside at our meeting. This cannot fail to have a good influence, as showing we have a Secretary of State not unmindful of the benefits conferred on India by the Western system of medicine and the untiring labours of the medical profession in that country.]

India was not slow to appreciate the importance of the movement; but at the beginning of this century the attention of all research workers in that country was chiefly directed to the visitation of plague that had commenced six years previously, and which then showed every sign of involving the country in unparalleled misfortune. The difficulties, the mistakes, the failures that naturally attended the efforts to control a disease about the methods of the spread of which we were then in helpless ignorance demonstrated the urgent need for medical research; but at the same time they tended to distract attention from the problems presented by other diseases of almost equal importance to the country.

Towards the close of the last century, and in the early years of the present, the Indian Medical Service was fortunate enough to attract

a number of men with a bent for medical research, who came to India fired by enthusiasm and determined to take full advantage of the unique opportunities that India offers for original investigation and scientific discovery. The service owes a debt of gratitude to Sir Almroth Wright, then Professor of Pathology at the Army Medical College at Netley, who did so much to fan the flame of this enthusiasm in all those who were fortunate enough to receive instruction and inspiration at his hands. At that time the Indian Medical Service could not boast of any special research department, but the investigations carried out, often in the face of considerable difficulty and with but little or no official encouragement, by individual officers such as Semple, Glen Liston, Rogers, McCarrison, and Mackie did much towards the creation of the present Bacteriological Department. This department was designed originally with a view to staffing the newly-created research laboratories in Bombay, Kasauli, and Madras as well as the Pasteur Institute of India. In recent years the department has developed considerably, and it now consists of twenty-nine cadre appointments, the majority of the incumbents of which are employed in research work, and have no other official duties to distract their attention from the problems under consideration. In addition to these, a considerable number of additional appointments are, as a rule, available in connection with special investigations and inquiries. Appointments in the Bacteriological Department are not reserved entirely for members of the Indian Medical Service. They are open to independent medical men possessing the necessary qualifications for medical research, and at the present moment six independent practitioners, one European and five Indians, have been admitted. The European (Dr. Gibson) is Director of the King Institute, whilst Drs. Turkhud, Soparkar, and Goré are working at the Bombay Bacteriological Laboratory, Parel, and Drs. Korke and Iyengar at the Central Research Institute, Kasauli, where another Indian gentleman, Mr. Awati, is working at the bionomics and classification of the various species of house flies. At present we have in India three research laboratories, at Kasauli, Bombay, and Madras respectively, and Pasteur institutes at Kasauli, Coonoor, and Rangoon, whilst two others will be opened in the near future—one at Shillong, and the other in connection with the Bombay Bacteriological Laboratory at Parel. All these institutes and laboratories are specially designed to offer facilities for post-graduate work and medical research. We shall shortly, moreover, possess two schools of tropical medicine in India—one at Calcutta and the other at Bombay. That at Calcutta is practically completed, and will be opened under the directorship of Sir Leonard Rogers as soon as the cessation of hostilities enables us to furnish the necessary professorial and teaching staff. The one at Bombay, which is being erected in connection with the Bombay Bacteriological Laboratory at Parel, is also approaching completion, and will shortly be opened under the charge of Major Glen Liston, the director of the above-mentioned laboratory. The Government of Madras, moreover, has under consideration a scheme for founding, in connection with the Madras Medical College, a pathological institute with provision for post-graduate and research work. All these institutions will offer unrivalled facilities for the investigation of tropical diseases. It may be mentioned, moreover, that attached to the Central Research Institute at Kasauli is a Malaria Bureau, which, under the charge of Major Christophers, is doing work of the greatest value. This remarkable progress, most of which has been effected within the last five years, is striking evidence of the importance that the Government of India attaches to medical research. The enthusiasm displayed on all sides augurs well for the future, and, provided that India continues to attract men with a leaning towards the scientific and research sides of their profession, there is no limit to the possibilities of the future.

Perhaps the most important of the more recent developments in medical research has been the establishment of the Indian Research Fund Association, which was founded in 1911. Generously endowed by Government, practically the only limit to medical investigation since its establishment has been the difficulty of obtaining a sufficient number of scientific workers of a suitable stamp. The association publishes its own journal—the *Indian Journal of Medical Research*—which has almost completed the third year of its existence. A reference to its pages will, I believe, offer striking proof of the valuable work already performed by the association. Numerous subjects have been dealt with, notably malaria, cholera, dysentery, yellow fever, kala-azar, the cinchona derivatives, plague, tuberculosis, bacteriological standards for tropical water supplies, diabetes, goitre, and leprosy, not to mention the various entomological investigations. The war has, of course, seriously curtailed the activities of the

association for the time being, but in spite of this the achievements of the past four years in India form a noteworthy page in the history of medical research.

Though much has been done, we have scarcely touched the fringe of all that calls for investigation. It is, indeed, a fascinating and, in parts, an almost unexplored field that calls for the attention of the research worker, and the facilities and opportunities offered are unique. There is scarcely one of the communicable diseases of India which will not repay further research. In the case of plague we require more accurate information as regards the remarkable immunity of vast tracts in India, chiefly on the east and in Burma, where rice-cultivation is predominant, also as to the part played by grain and grain godowns in the spread of the disease, and the influence of late-infected villages in carrying over the disease from one plague season to another, thus constituting epidemic foci during the following year. Numerous bacteriological problems connected with leprosy require further study, and much work still remains to be done in connection with the isolation and cultivation of the lepra bacillus, whilst recent observations justify the belief that there are important therapeutic possibilities in connection with the hypodermic injections of Chaulmoogra oil and of the salts of gynocardic acid.

Kala-azar has still to yield its epidemiological secrets, especially as regards its mode of transmission and its identity or non-identity with the infantile kala-azar of the Mediterranean littoral.

Rabies, too, presents many important problems for consideration. The Pasteur treatment of this disease, so far as India is concerned, has been revolutionised during the past few years by Semple's discovery of the value of anti-rabic inoculation by means of a carbolised dead virus, whilst researches are now in progress which may possibly lead to further improvements in this method of treatment. The work of Acton and Knowles, moreover, on snake-bite, which was conducted at the Pasteur Institute, Kasauli, has thrown new light on the subject of the use of antivenine, and has demonstrated the lines upon which further research is necessary if treatment by antivenomous sera is to be thoroughly successful.

During the last two years it has been demonstrated that relapsing fever is much more common in India than was realised formerly, and investigations are urgently required into the conditions favouring its development and spread in certain regions. Mackie's observations have demonstrated that the body-louse is the carrier of the ordinary type of this disease, and those of Nicolle have proved that transmission is due to accidental crushing of the lice, the mere bite being innocuous. Many problems, however, still remain unsolved, and we cannot regard *P. vestimentorum* as the only carrier of spirillar fevers in India. For instance, Browse has described an outbreak of an abnormal type of relapsing fever in Quetta, which he considers to be transmitted by *Argas persicus*, and Jukes has reported typical cases of spirillar fever in the Darjeeling district which closely resemble the remittent fever of Vandyk Carter, but in which a careful examination of lice and bugs from the infected houses failed to demonstrate the presence of spirochætes in these insects.

Then, again, the fevers of short duration and uncertain origin which in some respects show such striking affinities with yellow fever, and which under various local names are universally prevalent, urgently call for investigation, especially as regards the carriers of the disease, about which the greatest confusion prevails—some incriminating *Phlebotomus papatacci*, others *Culex fatigans*, and others again *Stegomyia fasciata*. There is also the important question as to whether dengue, Calcutta fever, Gilgit fever, etc., are separate entities, or whether they are modifications of one and the same disease. An investigation into all these points had already been planned when the outbreak of hostilities rendered it necessary to postpone this till a more suitable occasion. In this connection I may mention another important problem, namely, the relationship of *Stegomyia scutellaris* to yellow fever. Is it or is it not a carrier, and is there anything in the suggestion that by driving out *Stegomyia fasciata* one may protect a given locality from infection ?

The dysenteries have still their unsolved problems, both from the etiological and the therapeutical standpoint; whilst every day we realise more fully the importance of further research before we can recommend to Government the undertaking of extended and expensive anti-malarial measures, especially such as involve the clearing of jungle and the utilisation of the silt of the large rivers. New light has been thrown on the subject of jungle clearing by the investigations of Strickland in Malaya, and in view of the conflicting opinions expressed by Bentley and Fry in Bengal, Marjoribanks in Bombay, and Kenrick in the Central Provinces, it is evident that further research in this direction is eminently desirable. It is also

necessary that careful investigations should be made into the problems presented by malaria in Lower Bengal, as distinguished from that of Upper India, to enable us to arrive at a definite conclusion as to whether or no the malarial endemicity of the Gangetic Delta can best be dealt with by attempts at drainage and jungle clearing or by irrigation and utilisation of the silt of the large rivers, as in Egypt. In this connection there is a growing feeling that the silting up of these large rivers, with consequent agricultural depression and physical deterioration of the inhabitants, is a very important factor in the causation of the disease. Investigation, too, is required into the factors which are responsible for the seeming paradox that, whereas in some parts of India rice fields are harmless, in others they are highly malarious. There is, moreover, the important question of the causation of blackwater fever and its relationship to malaria, in connection with which the suggestive papers on "*Acidosis*" by McGilchrist, and on the "Hæmolytic point" by Christophers and Iyengar, offer valuable suggestions for future work.

Then, too, the flies of India, both blood-sucking and non-blood-sucking, the sand flies, the hook worms, the filaria and guinea worms, the larvæ-destroying fish and other natural enemies of the mosquito, the flagellates of plants, and the various parasitic fungi offer ample scope for research to the entomologist, the helminthologist, the botanist, the biologist, and the mycologist, whilst the pathologist will find his labours amply repaid by careful investigation into the various forms of pernicious anæmia (especially that peculiar disease called "sukhi", which follows child-birth), as well as into osteomalacia, infantile hypertrophic cirrhosis of the liver, the so-called "scurvy rickets," and beri-beri. The last mentioned deserves special attention, both from the general point of view of a deficiency disease and as regards its relationship to "epidemic dropsy." Other problems of vital importance are those connected with the possible fixing of bacteriological standards of purity for potable waters (a subject in which Morison is doing such good work at Poona); the question as to what extent, in view of Greig's recent work, cholera can be regarded as merely a water-borne disease; the probable connection of goitre with fœcal contamination of the water-supply; the comparative value of the various cinchona alkaloids; the therapeutic use of intravenous injections of metallic antimony, and the soluble antimonial preparations in the treatment of kala-azar; the possibility of substituting for the more expensive emetine the cheaper alkaloids of opium, such as narcotine and papaverine, as remedies for amœbic dysentery; and the investigation of the properties of indigenous drugs. As regards the last point, I may mention that it is intended to found a Chair of Experimental Pharmacology in connection with the School of Tropical Medicine at Calcutta.

We are indeed far from the goal towards which we are tending, but the future is big with promise. The possibilities are limitless. When the importance of medical research is still more widely recognised, when we realise the debt which the medical profession owes to itself, to its country, and to the millions of our fellow subjects in the outlying parts of our Empire, then medical research workers in tropical and sub-tropical climes will attract to themselves recruits from the best intellect of the profession. When this happens, let us hope that the claims of India will not be overlooked, and that the unique advantages offered by the Indian Research Fund and the Bacteriological Department of the Indian Medical Service, with their numerous research institutes and laboratories, will be estimated at their proper value.

I am not referring to the deeds of medicine and surgery, carried on whether in the teaching hospitals, the civil hospitals scattered broadcast through the length and breadth of the land, or to the travelling dispensaries which bring aid to the ryot at his door in far out-of-the-way villages. Nor do I mention that hard-worked man, the civil surgeon, who to be an asset to Government should be a man of character and personality—for such alone will carry out those works of supererogation so essential and for which money does not pay. This is a class to which Government owes much and the people of India more, but a class too often forgotten when honours are distributed! For such work as these officers carry on, the best medical men that this country can send are required.

DISCUSSION.

THE CHAIRMAN (the Right Hon. Austen Chamberlain, M.P.), in opening the discussion, said he was not competent to discuss the details of the paper, but there were one or two broad considerations to which he desired to refer. Sir Havelock had been good enough to remind him that he had an hereditary interest in the spread of learning connected with tropical medicine. When his father first went to the Colonial Office, and considered one of the great

hemispheres into which the activities of a Colonial Secretary were divided, he quickly came to the conclusion that if this country was to do its duty by its tropical dependencies it was of the first importance that the health of the people who went to them should be improved. We had been for so long accustomed to send our best to India that he was not sure it had always been recognised, or that those who went to India recognised, how much still remained to be done in that country in the light of modern progress in science and medical research. He was convinced that nowhere in the Empire was there a larger field for research and for fruitful experiment, which might be a blessing, a safeguard, and a protection against needless sacrifices and heartbreaking sorrow, not only for the men of our own race and the families that sent them forth, but for the peoples of the country itself. He was struck at the India Office with the scale on which Indian life was measured—with the scale on which nature worked there. To many of those present, who for long years had been familiar with Indian conditions, that sense of the magnitude of the populations that were being dealt with had lost its novelty and had become a commonplace; but to one who, like himself, came fresh to the consideration of Indian problems, there was something appalling in the scale on which the ravages of nature worked amongst the hundreds of millions of the populations of India—plague, famine, snake-bite—things which were far distant from the people of this country, but which claimed their victims in India, not by tens nor by the score nor by hundreds, but by thousands and tens of thousands. Whether one looked at the problem in the light of the vast mass of humanity whose interests were at stake, or whether one looked at it in the light of the numberless problems which were still unsolved and which awaited the willing worker, India offered a splendid field for research and for the service of mankind. There was a consideration which was equally applicable to all who worked in India, whether they were Europeans or Indians, but he wished to say a few words about the share of the European in the task in question. This country had always sent of its best to India. Nothing but the sending of its best would justify the position which we held and maintained; but never was it more necessary than at present that it should be the best that should go. This country had brought Western learning within the reach of Indians; it had invited them to share its pleasures and its mysteries, its temptations and its dangers. They had readily responded to the facilities which were put before them; they were taking an ever-increasing interest in those things, and would play an ever larger part in the development and the progress of their own country. That was the object of British government; that was one of the great reasons for which it existed. Just in proportion as we were successful, more was demanded of those who represented this country among them. Just in proportion as Indians qualified to take their part, the Englishman would only discharge the great responsibilities which rested upon him if he was of the very best that England could send, and nothing short of the best was good enough for India. He therefore made such appeal as he could to the leaders of the medical profession in this country to make themselves aware of the openings which service in India afforded, whether in the immediate practice of the profession, or in that interesting and most important research work with which the paper dealt. He appealed to the leaders of the profession and the teachers and heads of the great medical schools to make themselves acquainted with the opportunities that were offered by India, then to spread that knowledge among their pupils, and not to grudge to India some of the best pupils that were produced. It was necessary to recruit in this country. He was very conscious that, as a result of the war and the sacrifices made therein by the medical profession, there would be a greater call for doctors and a less choice in the years that immediately followed than there had been in the past. But if all had to go short, let all make some sacrifices. No one should think that all the best ought to remain at home, and that the second best were good enough to represent this country overseas. It was only with the goodwill of the heads of the profession that men could be recruited who would maintain the honour and the reputation of the profession in India and elsewhere throughout the Empire. It was of the first consequence, as a matter of Imperial policy, that that should be done; and it was partly to plead with the heads of the profession that they should at least encourage those who were inclined to take up a career in India, and give a proportion of their best students for that purpose, that he was present at the meeting that afternoon.

Sir Patrick Manson, G.C.M.G., M.D., F.R.S., desired to take the opportunity of congratulating the Society on having secured Mr. Chamberlain as the Chairman of the meeting. On such an occasion, as an advocate of tropical medicine, he was the right man in the right place, because the mantle of a distinguished parent had fallen on a distinguished son. He hoped that the Chairman would be as successful as his father in forwarding the interests of tropical medicine. There could be no question, considering the extent of the Indian Empire, its enormous population and variety of races, and its variety of climate, that it must include also an enormous variety of disease. That was due not only to the aggregations of huge masses of humanity, but to the insanitary conditions that existed, and

to the enormous variety of animals with which dignified man had so much in common. That was a community of interest which man was not very proud of talking about, but it was none the less true. Man was a beast, and the sooner he recognised that fact the better. It was a stab at his pride, but it was an encouragement to modesty. In the past he had had considerable experience in the study of tropical diseases in China, and he was there struck very forcibly with the latent capacity of the Chinese for studies of that kind. The capacity of the Japanese in that direction had already been proved, and there was a latent capacity in the Indian which would in due course be developed. With that object in view, he had strongly urged the encouragement of attempts being made by Indians at original investigations into tropical diseases. He thought that rewards of some sort—he did not say pecuniary rewards—should be offered sufficient to induce them to take up such a line of study. He suggested that there should be a multiplication of students in the medical colleges in India, and that special attention should be given by the teachers to qualify those men to act as original investigators. The Indian's brain was more subtle than that of an Englishman; his imagination was more active, while his manipulative skill was enormously greater than an Englishman's. When he was in practice in China he got a Chinaman who, after a little training, was able to do all his microscopic work, and he had not the slightest doubt that if the same thing was carried out in India it would be equally successful. He was exceedingly glad to hear that the Indian Government was encouraging research. When he was a young fellow, there was a rumour at home to the effect that any man who wanted to pursue medical studies in India would be more or less shelved—he would be looked upon as a troublesome man and not acceptable to the administration. Those bad days were over, and if proper appreciation of some sort were held out to European medical men in India, and especially to the native medical men, enormous strides would be made in the study of tropical medicine. He hoped that India would always possess as sympathetic a Secretary of State as the present one; if he was like his father in that respect it would be impossible to wish for more, because his experience of the late Mr. Joseph Chamberlain was that he was always willing to grant money for the carrying out of original research.

Sir Malcolm Morris, K.C.V.O., F.R.C.S.E., after congratulating Sir Pardey Lukis on his admirable paper, said that on his return home from a trip to India in 1914, he wrote an article in the *Times* on the subject dealt with in the paper. As a result he received an enormous amount of correspondence, some abusive and some the opposite, and it at once showed him that he had hit a point of the very gravest possible importance. He urged in that article, as strongly as he could write, that tropical schools of medicine should be established at Bombay and at Calcutta. He had been connected with the tropical school at the Albert Docks, and had lectured to students upon certain tropical diseases which he had never seen. He had also lectured on some which had come from the tropics to this country, therefore differing in many respects from what they were in their own country. After visiting India and seeing the very remarkable work that was carried on there, he came to the conclusion that the proper place for men to learn about tropical diseases was on the spot. It was well that there should be schools in England, like that at the Albert Docks and at Liverpool, to train men in the art of observation, so that when they went to the tropics they might be able to utilise the knowledge they had gained at home when carrying out the research. Sir Havelock Charles was right in his statement that investigators were born and not made, but there was something more than merely being born; there was something in being cultivated. A man had to be born with an instinct to become a doctor or a statesman, but it was no good being a doctor or a statesman unless one cultivated the art, as the Chairman had done. He (Sir Malcolm) was connected with an Indian family. His father was in the Indian Civil Service, and most of his relatives lived in India. In his childhood he remembered relatives coming home and dying of liver abscess and all kinds of tropical diseases. Many of those diseases were extinct at the present time. For instance, liver abscess was now practically unknown. That change had been brought about as a result of the research work carried out in India. Medical men had investigated dysentery and found that amœbic dysentery caused liver abscess. Years ago people said it was due to nothing else but "pegs," but it was not; it was due to an infection. That infection had been to a large extent stamped out, and the disease which had killed so many white men had almost entirely disappeared. That was to the credit of the men who had given up their lives to live in a disagreeable climate amid all kinds of difficulties; and if the people of this country would only give them sufficient encouragement to carry on that work and let them know that those at home appreciated the work they did in the East, the diseases of the East would fall away one after another with extraordinary rapidity. It was an astounding thing to him that, in the midst of a great war, it was possible to hold such a large meeting to discuss the subject of tropical diseases in India, and that the Secretary of State for India should preside over it. It only showed that the people of this

country were trying to fight disease in earnest, and were determined that England should stand in the forefront in the fight against disease when the war was over. But it was no good coming to meetings and doing nothing; it was absolutely essential to fight while the war was on, in order to be ready when the war was over. The terrible disease of leprosy existed throughout India, China, and other parts of the world, and no serious attempt up till quite recently had been made to stamp out the disease. Recently his friend Sir Leonard Rogers, of Calcutta, had begun a piece of work which, in his (Sir Malcolm's) opinion, would bring forth good fruit. When he was in India in January 1914, he saw an Englishman, a member of one of the Services in India, terribly afflicted with leprosy. He was treated by Sir Leonard Rogers at Calcutta, and on seeing that man within the last few months he found that he was absolutely well; every manifestation of the disease had disappeared, although time alone would show whether the cure was permanent. He had that day seen an officer in this country who was afflicted with leprosy, and who had been under observation for the past few months. He had been carrying out the treatment recommended by Sir Leonard Rogers, and the improvement was so remarkable that he had never seen anything like it before in his life, with the exception of the case he had mentioned. That was the first step up the ladder towards the cure of leprosy, and if the India Office and other Departments continued to encourage research he believed the thousands of miserable people in India who were afflicted with leprosy, who were at present taken care of by the religious societies in India with a little support from the Indian Government, would be cured.

The chair was then vacated by Mr. Chamberlain, and was taken for the remainder of the meeting by Sir William Duke, K.C.S.I., K.C.I.E.

Surgeon-General G. J. H. Evatt, C.B., M.D., R.A.M.C., desired to thank the Secretary of State for India for having presided over the meeting. The fact that he had done so would prove of enormous benefit to the Medical Service in India, as the prestige of the Secretary of State was a tremendous asset. It was the first time, so far as he was aware, that the Secretary of State had presided over any meeting of medical men, and it was a very important departure which would have the most far-reaching effects, not only on the people in this country, but on the millions of India. It was of particular importance in view of the fact that the prestige of the Indian Medical Service had latterly fallen rather into the background. The paper that had been read was of the utmost importance in connection with the many thousands of European troops who served in India, among whom at one time there was a large percentage of deaths, due largely to the want of sanitary conditions among the natives who surrounded the cantonments. Research in medicine in India would be of benefit not only to the natives, but also to the soldiers who served in all parts of the Empire.

Major R. McCarrison, M.D., F.R.C.P., I.M.S., said, as one who had enjoyed, during the past fifteen years of service in India, the opportunities for medical research to which Sir Pardey Lukis had referred, he desired to bear testimony to the enormous field which India afforded for such research to those who had a special aptitude for it. He could not hope to add much to the information which Sir Pardey Lukis's paper had provided, but he might be permitted to refer to one or two points dealing with the results achieved in the past and the bearing of these on the prevention and treatment of disease in the present war. He thought it was not too much to say that Ross's demonstration of the truth of Manson's hypothesis that the spread of malaria was due to the mosquito laid the foundation of all tropical sanitation. No better illustration of the far-reaching effects of his discovery could be afforded than the triumph of American tropical sanitarians in the Panama Canal zone. Those great engineers, the French, had failed in the gigantic project of constructing the Canal, not through lack of engineering skill, but through lack of that knowledge which the genius of Manson, and of Ross of the Indian Medical Service, had provided. It was this knowledge, so skilfully applied by Surgeon-General Gorgas, which made possible this feat of engineering skill, and converted one of the most pestilential places of the earth into one of comparative salubrity. Nor was it too much to say that methods of treatment of the dysenteries which had their origin in India had resulted in the saving of tens of thousands of lives in the present war. Buchanan's saline treatment of bacillary dysentery was for long the only reliable means of dealing with cases of this disease, and even now that serum therapy was recognised as a specific means of cure, it was still a weapon of such potent effect that we could ill afford to dispense with it. Rogers's discovery of the specific influence of emetine in amœbic dysentery, when employed hypodermically, had robbed this dread disease of half its terrors, reduced its mortality enormously, and been responsible for the almost complete absence of its dangerous sequel—liver abscess—amongst the numerous sufferers from this form of dysentery during the present war. Nor must it be forgotten that the work of Haffkine, of the Indian Service, in 1893-1897 in perfecting a method of prophylactic vaccination against plague and cholera, had provided a potent means of defence against those diseases. During the Gallipoli campaign our troops, who had

received the benefits of prophylactic inoculation against these diseases, remained wholly free from them, while they prevailed in the Turkish trenches in the near neighbourhood. It was largely to the impetus which Haffkine's work gave to research in connection with prophylactic inoculation by bacterial vaccines that we owed the success which had crowned this practice in the case of fevers of the typhoid group. With regard also to relapsing fever, which prevailed in Egypt, the knowledge of its epidemiology and means of spreading, which emanated from India, enabled medical officers to combat it with success. In Mesopotamia, which, so far as the speaker was aware, was the only theatre of war where cholera had prevailed amongst the British forces, its spread was limited and its cure greatly facilitated by methods which the profession of medicine owed to medical research in India. These, then, were amongst the benefits which Indian medical research had made available for friend and foe alike in the present conflict of nations. They were an augury of still greater triumphs over disease which the future held for research workers in India.

Colonel Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc., in proposing a vote of thanks to the author of the paper, and to Sir Havelock Charles for his kindness in reading it, said that the writer of such an interesting and able paper as that which had been read could have had no more eloquent exponent of it than Sir Havelock Charles. The Society was also pleased to welcome two very distinguished members of the India Office who had assisted in the discussion, and the Council of the Society would be only too pleased if at the discussions it was sometimes possible for the whole of the India Council to attend. Most of the papers read before the Indian Section of the Society were written by experts who had had long experience of the subjects with which they dealt, and who had had time to arrive at definite conclusions in regard to them.

Mr. Mirza Ali Abbas Baig, C.S.I., in seconding the motion, said that the opportunities for research in India were as vast and as varied as its population and its physical aspects. Among the multifarious blessings of British rule, none had been so manifest in its results as the application of Western scientific methods to Eastern conditions. He did not wish to disparage the native systems; they had their own methods of treatment which were sometimes most efficacious, as he knew from personal experience. But the native systems were practically stagnant when British medical men began their researches in India. Much was heard of the splendid work that was being done for India by the Indian Civil Service and by the engineers, but the quiet, unobtrusive and most beneficent work of the medical profession was not so well known nor appreciated. He was glad to hear the appreciation that had been expressed of the work of Haffkine by Major McCarrison. There was a great deal of prejudice in India against Haffkine perhaps, because he was a Russian Jew; but from his own personal knowledge he could fully endorse the encomiums that had been heaped upon him by Major McCarrison. The great problem in India at present was how to combat malaria, which was more destructive than all the other diseases combined. If the united genius of the medical profession in India could rid the country of that terrible scourge, it would be the greatest blessing that British rule could confer upon the country.

The resolution of thanks was then put and carried unanimously.

Sir Havelock Charles thanked the meeting, on behalf of the author and himself, for the very kind manner in which the vote of thanks had been moved, seconded and passed. In reply to Sir Patrick Manson's suggestion that Indians should be employed in the carrying out of scientific research, it might interest the meeting to know that of the twenty-nine appointments in the Bacteriological Department, six were held by outsiders, of whom five were Indians. The seconder of the vote of thanks had stated that the work of the Indian Civil Service and of the engineering profession in India was seen of man, but that the work of the medical men could not always be seen. Neither should it be seen, because the best work of the medical profession was that which was unseen. It was said of the women of ancient Greece that the best woman was the one with regard to whom nothing was said. That saying applied equally to the work done by the members of the Indian Medical Service. The work was not apparent in the press, nor in the public view, but in the households of the people. It was the personality of the civil surgeon that reached the heart of the Indian, and what more could be desired? That was what paid the civil surgeon for his onerous work. But it might be asked, was it good for a Government or a people ever to receive benefits and repay generally in words?

The meeting then terminated.

FIFTY YEARS OF INDIAN COTTON CROPS—1863-64 to 1912-13.

With Notes on the three last ones.

Area.

Only in the last five-and-twenty years have complete returns been officially published of the area under cotton, only about twenty of which apply to the half-century. Between the five-year periods ending 1897-98 and 1912-13, the quinquennial mean rose from $15\frac{3}{4}$ to $21\frac{1}{3}$ million acres,

equal to 36 per cent. The yield per acre on the official estimates improved from 64 to 76 lb., but on the "approximate crops" from 83 to 93 lb.

(The record crop of 1913-14, the first following the half-century, was gathered on an area of 25 million acres, equal to 85 lb. on the official estimate of 5,065,000 bales, but of 107 lb. on the approximate crop of 6,684,000 bales of 400 lb.)

Outturn.

In the twenty years ending 1882-83, the approximate crops averaged from 2 to 2¼ million bales, in the next five 2¾ million, followed by two of 3¼ million; in the subsequent one by nearly 3¾ million, and 4½ million in the next five, every year exceeding 4 and one 5⅓ million, while in the last five the average was just under 5 million.

(The crop of 1913-14, as just stated, approached 6⅔ millions, the following one 5¼ millions, and the last 5½ millions.)

In the last twenty years (of the fifty) the official estimates of yield—not previously issued—proved, on an average, too conservative by about 30 per cent. In the first five years ending 1897-98, they were too low by 850,000 bales (35 per cent.), in the next five by no less than 1,069,000 bales (41 per cent.), in the following period by 865,000 bales (23½ per cent.), and in the last by 913,000 bales (22⅔ per cent.).

Home Consumption.

Accurate returns of the quantities exported, as well as of the consumption by the mills, are available. Our notes are based on tables for the years ending June 30th, the end of the Bombay season, the export statistics being compiled from the returns of the Bombay Chamber of Commerce, and of the mills from those of the Bombay Mill Owners' Association. The only element of uncertainty is the local, other than mill, consumption. The official estimates regarding this have fluctuated in a remarkable manner, 400,000, 250,000, 750,000, and a year or two ago, after consultation with the Bombay Cotton Trades Association, a million bales. The data on which this estimate was arrived at have not been stated, but even if they are approximately correct the consumption of the country, for purposes other than spinning by the mills, has risen to 1¼ lb. per head. Half a century ago it was placed at 600,000 bales by Mr. Rivett-Carnac, the Cotton Commissioner of the Central Provinces and Berar. This was then equal to about 1 lb. per head. At that time the mill consumption was barely 65,000 bales, equal to about 3 per cent. of the two million bales produced, while the local consumption was equivalent to over 28 per cent. To-day the respective proportions are nearly 40 and 18 per cent. The mill consumption in the first half

* Estimate. † Official estimate.

of the fifty years rose from 3 to 23 per cent., in the next five to 33 per cent., in the following fifteen fluctuated between 41 and 43 per cent., and in the last five averaged 41 per cent.

(Of the large crop of 1913–14 the ratio fell to 32 per cent., but in the last two averaged about 39 per cent.—2,100,000 bales.)

EXPORTS.

During the first half of the fifty years the proportion of the crops exported—1¼ to 1½ million bales—of the total available supply fell from 69 to 53 per cent., in the next five (one million) to 46 per cent., in the following two quinquennial periods (1½ million) to 37½ per cent., then rose (2 million) to 42½ per cent., and in the last five years (2 million) to 43½ per cent.

(In 1913–14 over 53 per cent. (3½ million) were shipped to foreign countries, 41½ per cent. in the next year (2¼ million), and 44½ per cent. (2½ million) in the last.)

The opening of the Suez Canal in the middle of November, 1869, marked a great change in the direction in which Indian cotton was exported. In the five years ending 1867–68 nearly 69 per cent. was shipped—61½ per cent. to Great Britain, 4½ per cent. to the Continent of Europe, and 3½ per cent. to China and the Far East. Twenty years later the respective shares were 21, 30, and 2 per cent., the direct despatches to the Continent *viâ* the Canal rapidly reducing England's earlier re-export trade. In the last five years of the half-century the proportions had changed to 2 per cent. to the United Kingdom, 22 per cent. to the Continent, and 20 per cent. to Japan principally and the Far East.

(Of the 1913–14 record crop, Great Britain took but 2¾ per cent., the Continent 28½ per cent., and Japan, etc., 22 per cent., while last season, owing to the war, the respective figures were 2½, 7¾, and 34 per cent.—total, 44¼ per cent.)

IMPORTS.

India imports little cotton from other countries. In the first forty-eight years of the half-century they averaged 25,000 to 35,000 bales, the bulk from Persia. But in 1911–12 over 135,000 bales (of 400 lb.) were imported from America and Egypt, and 175,000 bales in the following year, dropping again in the last three to less than the former normal.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

British Colour-making. — The new British colour-manufacturing industry makes more progress than is popularly known. The output of coal-tar dyestuff increases in current quantity, despite an accident which severely hampered the production of alizarine. In quality the British makes are better than ever, and impartial witnesses give their admiration spontaneously to the success attained in standardising successive lots. The variety is increasing, and the production of fair quantities of an entirely satisfactory sapphirol, a bright blue for wool dyeing, is one event which can be noticed. The manufacture of fully half a dozen of the most complex and valuable colours has been mastered in a textile works, and one of these days the country will awaken to the discovery that surprising headway has been made under circumstances of the utmost difficulty. Preparations for a much greater production of intermediates and colours are well advanced, and the records of the progress made elsewhere give the feeling that English manufacturers are by no means doing badly. Probably much more money is being made by American colour-makers, but no available reports go to show that either they or the Japanese colour-producers are earning any good name for their dyes.

Artificial Silk.—Artificial silk has the same base as paper, and its manufacture is affected in a measure by the difficulty of receiving wood pulp. Fortunately, arrangements have been made to secure a specified supply during the next twelve months, and the export of articles manufactured with artificial silk should not suffer. Wood pulp is indispensable to viscose silk, and when applied to that purpose it is distinctly more thriftily used than in the manufacture of common paper. The calculation goes that the pulp consumed in manufacturing the £2½ millions of exported textiles containing artificial silk represents merely 2 per cent. of the completed value. The yarn made from viscose is of an outstanding brilliancy, so that comparatively little of it goes a long way in seasoning light cotton fabrics to the taste of the tropics. Proof of the perfection that has been attained in converting wood pulp into lustrous yarn may be found in the plain cloths now made with a face entirely composed of this material. The test is the most severe one that could be applied, and apparently no fault is to be found with the way that the fabric stands washing and ironing. The original silks dissolved upon washing, and their successors were spoiled by immersion in water, while the hot iron played havoc with the colour.

"*Ozone*" *Fibre.* — Artificial silk is still the only well-proven substitute for the natural fibre, and although new natural fibres continue to be proclaimed, their efficacy as alternatives to the old-established materials remains doubtful. Even the "ozone silk" discovered in Saginaw, Michigan, must be included for the present in this class, for the particulars rendered about it relate rather to the prospective profits than to the real utility of this curiously named fibre. Like the German typha, it can be raised on swamp land, but there is no absolute proof as yet that the fibre will fetch the dollar a pound

which would enable its happy cultivators to earn £200 per acre. It is neither an uncommon nor a good sign that the possessor of some recondite fibre should harp more upon its profits than its use.

Looms for Soldiers.—A scheme reported to have the sanction of the War Office has for its object the teaching of hand-loom weaving to disabled soldiers. Workshops are to be opened in various centres in Scotland, and in some cases looms are to be installed in the home. It is an attempt, apparently, to revive the idyllic days at the same time that the broken man is given a means of livelihood. It would be well if all such schemes were reviewed in the light of economic advantage. A hand loom in its essence is a power loom operated slowly by hand and foot, giving a low rate of production and conferring no clear advantage upon the quality of cloth produced. The work is, of course, more laborious than upon power looms, and superfluous labour is not in itself desirable for men of impaired strength. Were lathes, sewing-machines, or knitting-machines, to be erected in any number in a workshop it is certain that nobody would think of driving them by hand if power could be raised or borrowed, and the reason for an exception in the case of looms is not evident. If looms are not grouped in workshops but scattered in cottages, there is the by no means inconsiderable labour of fetching materials to be woven and delivering the woven cloth. It must be submitted that these features are disadvantageous to a scheme of which the first purpose is the well-being of the workman, and they are assuredly not necessary ones.

A Cotton Annual.—The reappearance of the *Cotton Year Book* of 670 pages, additional to its advertisements and diary, might provoke a doubt of the actuality of the paper famine, and all the more as its price is the exiguous half-crown charged for its slenderer predecessors in less expensive days. The book grows with the developments, mechanical and commercial, of which it treats, and nothing else that is published gives so full an insight into the work of the industry. A volume first for the reference of people engaged with cotton, it is suggestive to other manufacturers and invaluable to seekers of an explanation. The manufacture of textile machinery, other than for specially approved purposes, may be in suspense, but the interest in alternative systems is very much alive, and in keeping the ball rolling an annual like the *Cotton Year Book*, 1917, renders inestimable service.

Burmese Specimens.—It is rather with clothes than cloths that Miss Laura E. Start deals in "Burmese Textiles" (Bankfield Museum Notes, F. King, Halifax, 3*s.* 6*d.*). The materials are Shan and Kachin garments collected by Mr. E. C. S. George, C.I.E., and made and worn by tribespeople living largely out of the world. The account is an eminently painstaking description of native needlework and native wear, with illustrations clearly exposing the ornamentation, and with dimensions stated to the fraction of a centimetre. The selection sustains the author's high opinion of the taste and fertility of the craftswomen, and it may be hoped and believed that the pains taken over the description will in due time form material for the comparative study of design.

Mill Life.—The idea that aptitude for textile work is hereditary among families resident in the textile areas is as well received there as elsewhere. Proof or disproof is hard to get, and the point frankly rests on opinion. It is, however, hardly a matter of opinion that those reconcile themselves best to mill life who have gone to the mill from early years, seen their friends and relations going, and have grown up to accept mill conditions as normal. Those who stay best at the work become naturally the best workers, and it is at any rate arguable that environment counts for as much as heredity and is more clearly traceable. The case exhibits itself in particular as well as in general, and notably in the willingness to live in one district and work in its mills, although not in those of a short distance away. The town-dweller can barely be persuaded to stay in mills called "in the country," and newcomers from beyond the textile radius can hardly be induced to make the mill their final destination. The matter is more one of amenities than of wages. His own district has given the employer his best workers hitherto, but it would be useful to know how much of this is due to an unattractiveness which repels those who have not been born in the surroundings. These conditions react on the minds of native girls and boys, who shun the occupations for which they have a reputed hereditary skill to devote themselves to trades in which they start at no advantage. The necessity for making the mill a more obviously agreeable place in which to earn a living is heightened by the proposals to raise the school age. In general, the reluctance to enter the factory increases with age and education, and the preference of those who should provide the detail labour will inevitably have to be met.

OBITUARY.

LORD ALLERTON, F.R.S.—The death of Lord Allerton took place on the 4th inst. at his residence in London.

William Lawies Jackson, first Baron Allerton of Chapel Allerton, Leeds, was born at Otley in 1840.

After being educated at a Moravian school, he devoted his energies to tanning, and became a prominent member of the leather industry. In 1876 he unsuccessfully contested the Parliamentary Division of Leeds, but four years later he became one of the members. In 1885 the city was rearranged into five divisions, and he was elected for the Northern Division, which he continued to represent until 1902, when he was created a Baron. He was Financial Secretary to the Treasury in 1885-86 and from 1886 to 1891, and Chief Secretary for Ireland in 1891-92. For over twenty years he was Chairman of the Great Northern Railway Company; he was also Chairman of the Royal Commission on Coal Resources, and of the South African Commission in 1896.

Lord Allerton was elected a member of the Royal Society of Arts in 1885.

GENERAL NOTES.

Victoria and Albert Museum.—Earl Beauchamp has lent for exhibition at the Victoria and Albert Museum the important collection of miniatures and snuff-boxes from Madresfield Court. The exhibition contains 372 miniatures in water-colour, oil, and enamel, by English and foreign artists, chiefly of the sixteenth, seventeenth, and eighteenth centuries, together with thirty-one snuff-boxes, chiefly French, and dating from the eighteenth century. It is arranged in Room 84, adjoining that in which the miniatures lent by the Duke of Buccleuch are exhibited (Room 83), and visitors will find in the collections shown in these two rooms representative examples of the work of practically every English miniature artist of importance of the sixteenth, seventeenth, and early eighteenth centuries.

Camphor.—The production of camphor in Japan for the year ending March 31st, 1917, is estimated, by H.M. Commercial Attaché at Yokohama, at 1,627,422 kin,* an increase of 26,607 kin as compared with the actual yield in 1915–16, while the estimated production in Formosa amounts to 5,014,743 kin, an increase of 394,561 kin, as compared with the actual yield in the preceding year. The production of camphor oil in Japan for 1916–17 is estimated at 3,210,494 kin, an increase of 209,073 kin as compared with the actual yield in 1915–16; the estimated production in Formosa is 7,827,560 kin, or 946,328 kin in excess of the actual yield in 1915–16.

Piassava Industry of British West Africa.—West African piassava is a brush-making fibre obtained from the leaf-sheaths of the wine-palm (*Raphia vinifera*). It is produced in most of the British West African possessions, but chiefly in Sierra Leone. The exports of piassava from that colony in 1914, according to the *Bulletin of the Imperial Institute*, were 983 tons, valued at £19,492, as compared with 839 tons, valued at £12,280 in 1913. The exports from Nigeria were 403 tons, valued at £5,117 in 1914, as compared with 228 tons, valued at £2,806 in 1913. No exports of the fibre from Gambia or the Gold Coast have been recorded in recent years, but the industry in Gambia appears to be worthy of attention with a view to development. The palm grows on the banks of the river, which is navigated by ocean-going vessels.

* A kin is 1·3 lb.

Sugar in Hong-Kong.—In a report on the Hong-Kong sugar trade, the American Consul-General mentions that the Chinese Government has been conducting experiments for some time with a view to introducing sugar-beet culture in China. Experiments have been greatly interfered with by the difficulty of securing seed, which is said to have increased in price from $8 to $58 per bushel, with very little to be had at any price; but sugar experts in Hong-Kong are of the opinion that the day is not very far distant when China will produce most, if not all, of the sugar required for its people, and thus release a large amount of Java and Philippine sugar for use in other parts of the world.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

April 18. — Horace M. Thornton, M.I.Mech.E., "The Application of Coal Gas to Industry in War Time: its National Importance." Sir George Thomas Beilby, LL.D., F.R.S., Chairman of the Fuel Research Board, will preside.

April 25.—Sir Francis Fox, M.Inst.C.E., "Flour and Bread." Captain Charles Bathurst, M.P., Parliamentary Secretary, Ministry of Food, will preside.

May 2.—J. C. Shenstone, F.L.S., M.P.S., "Herb-growing in the British Empire: its Past, Present, and Future."

May 9.—Professor William Ripper, D.Eng., D.Sc., Vice-Chancellor of the University of Sheffield, "Works Organisation and Efficiency." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

May 16. — Sir C. Arthur Pearson, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, Address on "The Blind Sufferers from the War, and their future Employment."

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

April 19.—R. S. Pearson, I.F.S., F.L.S., Imperial Forest Economist, "The Industrial and Economic Development of Indian Forest Products." Sir Robert W. Carlyle, K.C.S.I., C.I.E., Member of the Viceroy's Council, 1910–15, will preside.

May 17.—D. T. Chadwick, I.C.S., "The Future of Indian Trade with Russia."

Howard Lectures.

Monday afternoons, at 4 p.m.:—

William George Fearnsides, M.A., F.G.S., Sorby Professor of Geology, University of Sheffield, "The National Shortage of Iron Ore Supplies." Two Lectures. (1) Available Home Supplies of Iron Ore; (2) Overseas Iron Fields which Supply the British Market.

April 30, May 7.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 16...Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. J. I. Munro, "The Witness of Philology to the Truth of the Old Testament."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Mr. J. G. Head, "The Effect of War Conditions on Urban Property."

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 6.45 p.m. Mr. C. Vernier, "Wayleaves."

Tuesday, April 17...Petroleum Technologists, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. H. S. M. Jack, "The Development of the Petroleum Industry in Assam."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. R. Beazley, "Russian Development. Lecture I.—The Old Free Russia."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Annual General Meeting.

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 3.30 p.m. Annual General Meeting.

8 p.m. Mr. F. de Jong, "Ornamental Plastering and Decoration."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mrs. L. I. Veley, "Some Aspects of Animal Photography."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m.

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. C. D. Sherborn, "The Original Fragments of Skin of the Gorilla sent by Du Chaillu to Owen, from the Gaboon, 1862." 2. Mr. E. Heron-Allen, Lantern Exhibition illustrating the Mussel-fishery and Foraminifera of Esnandes (La Rochelle), and the early work of Alcide d'Orbigny.

Wednesday, April 18 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. H. M. Thornton, "The Application of Coal Gas to Industry in War Time: its National Importance."

Aeronautical Society of Great Britain, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Dr. W. H. Hatfield, "Steel and Steel Alloys."

Meteorological Society, 70, Victoria-street, S.W., 5.30 p.m. 1. Mr. E. G. Bilham, "The Diurnal Variation of Atmospheric Pressure at Benson, Oxon., during 1915." 2. Lieutenant C. D. Stewart, R.E., "Atmospheric Electrical Phenomena during Rain."

Geological Society, Burlington House, W., 5.30 p.m. Professors H. H. Swinnerton and A. E. Trueman, "The Morphology and Development of the Ammonite Septum."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor W. de la Mare, "The Sea in English Fiction."

Thursday, April 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. R. S. Pearson, "The Industrial and Economic Development of Indian Forest Products."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Dr. D. H. Scott, "The Heterangiums of the British Coal-Measures." 2. Mr. E. S. Goodrich, "Hypophysis and Premandibular Cavities: a Suggestion." 3. Miss N. Layard, "Wooden Scratching Tools made by an African Parrot; illustrated with specimens and lantern-slides."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Rev. R. R. Hyde, "Welfare Work with Young Employees."

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. E. Newbery, "The hydration of ions and metal overvoltage." 2. Mr. H. Nomura, "The pungent principles of ginger. Part I.—A new ketone, zingeribone, occurring in ginger." 3. Messrs. P. C. Ray, M. L. Dey, and J. C. Ghosh, "Velocity of decomposition and the dissociation constant of nitrous acid." 4. Mr. F. L. Pyman, "The alkaloids of ipecacuanha." (Part II.) 5. Messrs. R. O. Griffith, A. Lamble, and W. C. McC. Lewis, "Studies in catalysis. Part VI.—The mutual influence of two reactions proceeding in the same medium." 6. Mr. W. C. McC. Lewis, "Studies in catalysis. Part VII.—Heat of reaction, equilibrium, constant and allied quantities from the point of view of the radiation hypothesis." 7. Mr. A. H. Salway, "Note on the isolation of methylnonylketone from palm kernel oil." 8. Mr. J. N. Rakshit, "Metallic derivatives of alkaloids."

Royal Institution, Albemarle-street, W., 3 p.m. Professor H. S. Foxwell, "Industrial Finance after the War. Lecture I.—The Character of the Industrial Struggle of To-day."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m.

Historical Society, 22, Russell-square, W.C., 5 p.m. Mr. H. P. Biggar, "Charles V. and the Discovery of Canada."

Numismatic Society, 22, Albemarle-street, W., 6. p.m.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. 1. Mr. W. Whyte, "Stope Measurement at Messina." 2. Mr. F. Gillman, "Platinum in Spain."

Friday, April 20 ... Royal Institution, Albemarle-street, W., 5.30 p.m. Professor R. H. Biffen, "The Future of Wheat-Growing in England."

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, Westminster, S.W., 6 p.m. Address by the President.

Saturday, April 21...Royal Institution, Albemarle-street, W., 3 p.m. Professor G. H. Bryan, "The Principles of Aerial Navigation." (Lecture I.)

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—April 13, 1917.

Journal of the Royal Society of Arts.

No. 3,361. VOL. LXV.

FRIDAY, APRIL 20, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 25th, at 4.30 p.m. (Ordinary Meeting.) SIR FRANCIS FOX, M.Inst.C.E., "Flour and Bread." CAPTAIN CHARLES BATHURST, M.P., Parliamentary Secretary, Ministry of Food, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, April 19th, 4.30 p.m.; SIR ROBERT W. CARLYLE, K.C.S.I., C.I.E., Member of the Viceroy's Council, 1910-15, in the chair. A paper on "The Industrial and Economic Development of Indian Forest Products," by R. S. PEARSON, I.F.S., F.L.S., Imperial Forest Economist, was read by Laurence Mercer, C.I.E., late President, Imperial Forest Research Institute and College, Dehra Dun.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING.

WEDNESDAY, APRIL 18th, 1917; SIR GEORGE THOMAS BEILBY, LL.D., F.R.S., F.I.C., F.C.S., Chairman of the Fuel Research Board, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Baker, Arthur, Denehurst, Darwen, Lancashire.

Datta, Gour Chandra, 14, Waverley House, Kenton-street, Russell-square, W.C. (1)

Field, Wilford, Ivydene, Heston, Middlesex.

Ho Tung, Sir Robert, J.P., The Neuk, 83, Peak, Hong-Kong, China.

King, William W., Messrs. Typke and King, Ltd., Crown Chemical Works, Mitcham Common, Surrey.

Lim Peng Siang, 61, Kling-street, Singapore, Straits Settlements.

McKillop, Arthur Torrens, Ministry of Agriculture, Cairo, Egypt.

Patuck, Rustom Sorabji, The Vizianagram Mining Company, Chipurupalle P.O., Vizagapatam, Madras, India.

Shroff, Shiavaxsha Darabsha, Patel Mansion, Cumballa-hill, Bombay, India.

Smith, Robert Tweedy, 89, Chancery-lane, W.C. (2)

Vidyabhushan, Dr. Lingish (Shri Mahabhagavat), Ph.D., Kurtkoti, Dharwar, Bombay, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Brunjes, Thomas Alfred, F.C.S., M.S.C.I., 94, Waller-road, New Cross, S.E. (14)

Casson, Herbert N., 4, Lincoln's Inn Fields, W.C. (2)

Gardiner, Frederick Ambrose, F.L.S., 12, The Ridgeway, Golders Green, N.W. (4)

Hyett, John E., A.R.C.A., 4, St. Oswald's Studios, Sedlescombe-road, West Brompton, S.W. (10)

Noronha, Edward Joseph, J.P., Messrs. Noronha & Co., Hong-Kong, China.

Vickery, James Harris, LL.B., 4, Lincoln's Inn Fields, W.C. (2)

The paper read was—

THE APPLICATION OF COAL GAS TO INDUSTRY IN WAR TIME: ITS NATIONAL IMPORTANCE.

By HORACE M. THORNTON, M.I.Mech.E.

When I read my last paper before the Society, "The Uses of Coal Gas for Industrial Purposes"—now over two years ago—I then suggested that we were witnessing the dawn of a new era in industrial heating. On that occasion illustrations were given, by lantern-slides, of about seventy applications of coal gas to our largest national industries, representative of a very

much greater number known to be in operation. In spite of these already numerous uses, industrial gas was then merely in its early development, and the realisation of the universality of its service was only growing gradually upon the manufacturers of this country. To-day he would be a bold man indeed who would define the limits of its penetration. The extent to which British industries, and therefore the nation at large, are under tribute to this great servant of the twentieth century is very much clearer now than it was even two brief years ago. It is probable that two years of war have taught us, as a nation, more than two decades of peace. Much that we have been forced to learn we would willingly forget; but if there are to be found any valuable products from this time of outpouring of life and treasure, one of the chief will surely be the great progressive movements which, under the stress of war-time conditions, have characterised our foremost industries. It has been so with industrial gas. Uses hitherto unknown have been discovered, uses hitherto regarded as impossible have been proved successful. Town gas, of which we thought we had known the full story for many years, and the decline in the use of which had often been prophesied—that common and ordinary lighting, cooking, and heating agent, delivered to us so simply through pipes into our homes—has proved to be much more potent and far more serviceable than our familiarity with it allowed us to conceive. To-day I wish to take up the story where I left it on the occasion of the last paper in March, 1915, and to give some account of the progress that has been made in the interval. At that time I gave, among details of many industries, particulars of a few of the uses of gas that were in operation for the production of armaments and munitions of war generally. To-day, so extensive are the uses of gas for these purposes, that they provide more

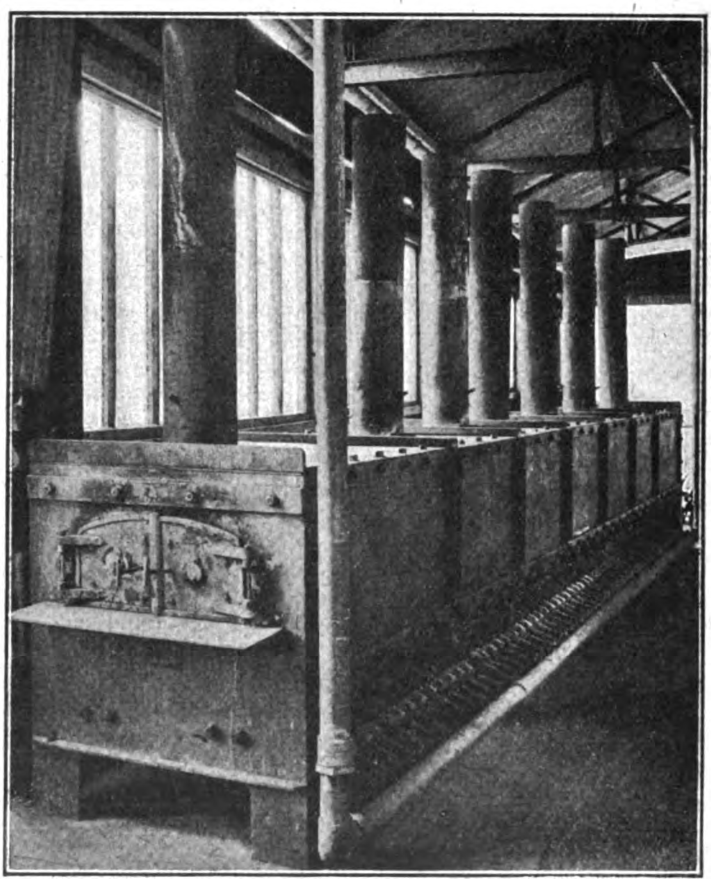

FIG. 1.—ANNEALING TOOL-STEEL BARS IN OVEN FURNACE, 22 ft. 6 in. long.

than sufficient material for this paper—indeed, it is necessary, if your patience is not to be unduly tried, to restrict ourselves in the first place to a consideration of the uses of the gas furnace in the engineering world, omitting the wide application of this fuel to the glass, cotton, cloth, hat, boot, confectionery, food and many other trades, with which I dealt in my last paper and which have during the last two years found still further scope for the utilisation of gas. I also desire to devote some time to the modern movement in regard to welfare work in factories and the part that gas plays in this important subject.

achieved with the utmost speed and in the face of an already heavy withdrawal of labour for military requirements. Under the stress of this need of maximum quantity with minimum labour at maximum speed many a manufacturer requiring a heat-treatment process—and heat is a well-nigh universal necessity in manufacture—sought and found the solution to his problem in the use of gas.

Let us look a little more closely into the facts as presented to industry when the demand for munitions of all kinds became insistent, and we shall see the part that gas for production purposes has played.

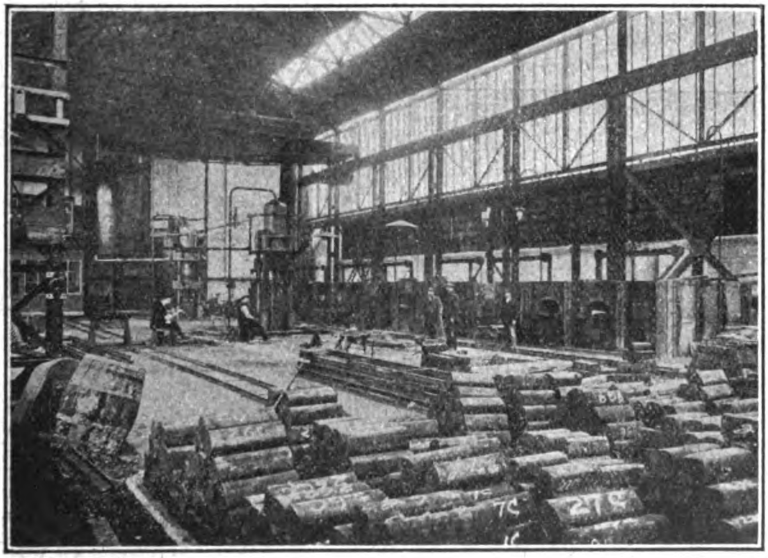

FIG. 2.—BILLET HEATING IN COKE FURNACE.

SOME REASONS FOR THE POPULARITY OF THE GAS FURNACE.

Before passing to the examples I wish to give and the illustrations I have to show, it will be of interest to trace some of the reasons which have led to the result I have described. Numerous and complex problems faced the engineers and manufacturers of this country anxious to respond to the call for "munitions, more munitions, and still more munitions." In many cases it was the problem of an immediate and enormous increase in normal production; in others, in many others, it was the problem of converting factories from the production of peace-time commodities to the turning out in vast quantities of war-time necessities.

Whatever the circumstances, the demand was for increased productivity, multiplied many-fold on ordinary output, and this was required to be

1. The volume of labour was reduced and, as events have proved, the manufacturer had to be prepared to face a still further decline. The gas furnace economised valuable labour, as no stoking was required; no fuel had to be transported or stored; no clinkering had to be done; no ashes had to be removed; very much less time was lost waiting for the furnace to heat up.
